The whole theory of the author of the *Vestiges* as to organic nature has been exposed to objection in consequence of its connection with views of the general system of the universe altogether foreign to the present subject; and because of an evident inclination to the belief in a transition from inorganic to organic existence by chemico-electric operation. The argument is also weakened by the too ready acceptance of unsubstantiated facts, as of the transmutation of one kind of grain into another; and by resting too much on what may be reckoned the mere mistakes of naturalists, as to the forms of the lower kinds of plants and animals, of which genera and even tribes have been constituted, that have afterward been found to be mere modifications or larval stages of creatures very different in their most apparent characters. Much hostility has been also excited by the extension of the theory of development to the human species, connecting man with pre-existing and inferior forms of animal existence. All this has been avoided by Darwin, by whom, however, the chief arguments of the *Vestiges* are used with great scientific caution.

Darwin's views are distinguished by the introduction of what he designates the prin-

ciple of *natural selection*. He maintains the variability of species, and adduces much evidence to show that variation is continually taking place in consequence of the external conditions to which plants and animals are subjected. He rests much on the difficulty of distinguishing between varieties and species, and on the changes which are known to result from cultivation and domestication. He dwells on the *selection* which man makes in order to produce new breeds or varieties, and supposes a similar "selection" to take place in nature, in the *struggle for life*, which all plants and animals must undergo. This *struggle for life* is, in fact, the foundation of his theory. He shows that every kind of plant or animal must maintain it, and in order to its continued existence, must be successful in maintaining it not only against those other creatures which seem to make it their food, but still more in a competition with those which seek the same nutriment with itself. In this struggle the stronger, or those which possess anything peculiarly favorable in their organization, must overcome the weaker, and these must therefore cease to exist. Thus a slight variation, such as often takes place, may be perpetuated; and the possessors of any advantage in the means of procuring food, or in the powers of offense or defense, may entirely displace their less favored congeners. The modifications thus taking place Darwin regards as accounting for the changes in organized beings from one geologic period to another, and for the great differences in the plants and animals of different parts of the world. In support of his views, he argues from the tendency to variation seen in cultivated plants and domestic animals, and the perpetuation of the forms so produced in breeds and races; and from the fact that the variations in cultivated and domestic species are in some cases greater than those which are regarded as affording grounds of specific, and sometimes even of generic or greater distinctions in a state of nature. "Can it be thought improbable," he says, "seeing that variations useful to man have undoubtedly occurred, that other variations useful in some way to each being in the great and complex battle of life, should sometimes occur in the course of thousands of generations? If such do occur, can we doubt—remembering that many more individuals are born than can possibly survive—that individuals having any advantage, however slight, over others, would have the best chance of surviving and of procreating their kind? On the other hand, we may feel sure that any variation in the least degree injurious would be rigidly destroyed. This preservation of favorable variations and the rejection of unfavorable variations, I call *natural selection*. Variations neither useful nor injurious would not be affected by natural selection, and would be left a fluctuating element, as perhaps we see in the species called polymorphic." He further supports these views by pointing out the favorable opportunity for the operation of natural selection afforded in a country undergoing great physical changes, as of climate; and particularly in an island, or a country surrounded by barriers sufficient to prevent the ready immigration of species. "In such cases," he says, "every slight modification, which in the course of ages chanced to arise, and which in any way favored the individuals of any of the species by better adapting them to their altered conditions, would tend to be preserved; and natural selection would thus have free scope for the work of improvement."

Mr. Darwin supposes new variations to be continually taking place, but the greater number of these speedily to become extinct; while others, becoming perpetuated, and perhaps causing the extinction of the original forms, again give rise to other forms, until some of them have so widely diverged that all traces of their common origin are lost. He does not, however, commit himself to the opinion that all forms of organic life, or even all plants, or all animals, have a common origin. He completely rejects Lamarck's notion that new and simple forms are continually being produced by spontaneous generation. "I need hardly say," he remarks, "that science in her present state does not countenance the belief that living creatures are now ever produced from inorganic matter," and he accounts for the existence of low forms of life by saying that "natural selection includes no necessary and universal law of advancement or development; it only takes advantage of such variations as arise and are beneficial to each creature under its complex relations of life." So that even the lowest forms might "be left by natural selection unimproved, or but little improved," as geology tells us of infusoria and rhizopods which have remained for an enormous period in nearly their present state.

That species differ not only in single characters, but in many, Mr. Darwin accounts for by reference to unknown laws of the correlation of organs—laws, however, which, although unknown, we know to exist, so that a modification of one organ is attended with modification of other organs, as is exemplified in our domestic breeds.

In further support of the theory of natural selection, the fact is insisted upon, "that it is the common, the widely diffused, and widely ranging species, belonging to the larger genera within each class, which vary most." That the several subordinate groups in any class of creatures "cannot be ranked in a single file, but seem rather to be clustered round points, and these round other points, and so on in almost endless cycles," Mr. Darwin thinks incapable of explanation, except on the supposition of community of origin and natural selection. He points also to the analogous manner in which species of the same genus vary, as corroborative of his views. He accounts for the absence or rarity of transitional varieties by supposing the predominant forms to have taken possession of their districts, while these were in process of being stocked; and that these districts, differing much in their natural characters, the forms originating in the com-

paratively unextensive intermediate tracts, have not been able to contend against them, and have become extinct. He points out the possibility that areas now continuous may not have been so during a long period, and that species may have been formed while they were broken up into islands. But this remains a chief difficulty of his theory.

He ascribes to natural selection the results which Lamarck ascribed to use and disuse in the development and atrophy of organs; and thinks it not impossible that the flying squirrels may thus have had a common origin with the true squirrels, and the *galeopithecus* with the lemurs, although he admits that we have no graduated links of structure connecting them together. "Nor can I see any insuperable difficulty," he says, "in further believing that the membrane-connected fingers and forearm of the *galeopithecus* might be greatly lengthened by natural selection; and this, as far as the organs of flight are concerned, would convert it into a bat." Like Lamarck and the author of the *Vestiges*, Mr. Darwin rests not a little on the unity of type throughout whole classes of creatures, and the homologies of parts very different from each other, as in the four-limbed structure of the vertebrata generally, and even the articulations of the limbs. He endeavors to trace the eye from its simplest to its most perfect form, and shows how gradual are the transitions found on comparison of existing creatures, from the one to the other. He goes even further, and says: "Several facts make me suspect that nerves sensitive to touch may be rendered sensitive to light, and likewise to those coarser vibrations of the air which produce sound."

He dwells at great length on the subject of hybridism, and the general sterility of hybrids, endeavoring to show that it presents no insuperable objection to the theory of a gradual modification of species, their sterility being incidental on other differences, and sterility occurring, as he labors to prove, when varieties are crossed, as well as in the hybrids of distinct species. The difficulties presented by geology he obviates very much by insisting on the imperfection of the geological record. He does not adopt the view of the author of the *Vestiges*, that the geological record exhibits to us a succession of animals corresponding in their progressive development with the fetal development of the mammalian embryo. But he founds an argument on the many connecting links in the general system of nature which fossils supply when compared with existing species. And he endeavors to show that his theory is perfectly consistent with the known facts of the geographical distribution of species, and in particular with the remarkable facts of the peculiarity of the fauna and flora of some of the lonely oceanic islands, and of the frequent occurrence of the same species both in cold regions comparatively near the pole, and on mountains far remote from each other in lower latitudes; referring the latter class of facts to former geologic periods, when the continental areas were not the same as now, or when the prevailing climatic conditions were very different. And he finds support for his views in the correspondence, without identity, of the floras and faunas of the northern parts of America and of the Old World.

It is but a very imperfect sketch which we have thus been able to give of Darwin's theory, and of the arguments by which it is supported. Whatever may be thought of the truth of the theory, it must be admitted to be admirably framed and guarded, and to be maintained not only with great ingenuity of argument, but by the aid of a vast store of scientific information, most skillfully used. Its opponents condemn it as resting on unwarrantable assumptions, and demand some proof, for example, of the transition of organs from a simple or rudimentary to a complex and more perfect state. They also refuse to acknowledge such imperfection of the geological record as Darwin's argument demands, and they insist much on the completeness of the changes which that record discloses, and the absence of transitional forms both among fossils and existing species. Much of what Darwin and other advocates of the same general views contend for, they admit; a certain power of development in organic nature, a "struggle for life," and "natural selection;" but they regard the limits of development and variation as comparatively narrow. Nor would the state of the question, as they believe, be materially affected, if many of what have hitherto generally been regarded as species, should be proved to be mere varieties. Any number of such errors of naturalists might be exposed and corrected, without modification of our views of the laws of nature; and errors of this kind are precisely such as might be expected, when the forms of organic life began to be discovered and described, and ere yet there was time for their mature study in all parts of the world, and under all various circumstances.

The doctrine of Darwin, or the *Evolution Theory* as it is usually named, continues to be a fruitful source of controversy. It has found many adherents in all countries, and its leading principle—"the survival of the fittest"—has been applied in other fields of inquiry besides natural history. It ought to be mentioned that the eminent naturalist, A. R. Wallace, unaware of the speculations Mr. Darwin was engaged in, had elaborated independently a very similar scheme; and the prior publication of Darwin's labors was chiefly accidental. Darwinism has made the most remarkable progress during recent years. Scarcely a living naturalist now entirely rejects it, and the vast majority indeed are earnestly occupied in its elucidation and application. It should be remembered, however, that this is not the only possible theory of Evolution. See articles on DARWIN; DARWINISM; ZOOLOGY; MAMMALIA; etc.; as also Darwin's *Origin of Species*, *Descent of Man*, and other works; Lyell's *Principles of Geology*; Huxley's *American Addresses and Science and Culture*; Haeckel's *Natural History of Creation*; Meurier's *Le Darwinisme*, SPENCER, HERBERT.

SPECIFIC DISEASES. See **VENEREAL DISEASES.**

SPECIFIC GRAVITY of any body is the proportion which the weight of a certain bulk of that body bears to the same bulk of another body, which is taken as a standard. The standard for substances solid and liquid is distilled water at the temperature of 62° Fahr., barometer 30 inches; and the weight of a cubic inch of this standard is given in the Parliamentary Reports for 1825 as 252.456 troy grains, hence a cubic foot of it weighs 997.129 avoirdupois ounces, or 62.32 avoirdupois pounds. It is convenient to remember that a cubic foot of water weighs about 1000 ounces avoirdupois, as the error resulting from employing this estimate does not amount to much more than $\frac{1}{350}$ th of the whole. For æriform bodies, the standard is atmospheric air, a cubic inch of which, at a temperature of 32° Fahr., weighs .32698, and at 60° Fahr., .30935 grains troy. The specific gravity of solid bodies is best measured by the hydrostatic balance—a figure of which is given under Archimedes, Principle of (q.v.)—which gives the weight of a volume of water equal in bulk to the solid, by which it is only necessary to divide the weight of the solid in air to obtain the specific gravity; that of liquids may be obtained by the areometer (q.v.), or by comparing the weight lost by a solid body in the liquid and in water, and dividing the former by the latter—or by means of the *specific-gravity bottle*, which holds exactly 1000 grains of distilled water in its standard condition. The bottle is emptied of water, filled with the liquid, and then weighed; the result gives the weight of a volume of the fluid equal in bulk to 1000 grains of the standard, and hence this weight divided by 1000 gives the specific gravity. The specific gravity of an æriform fluid is determined by weighing a glass globe filled first with the fluid and then with atmospheric air. Annexed is a table of the specific gravity of a few of the more common substances:

SPECIFIC LEGACY. See **LEGACY.**

SPECIFIC PERFORMANCE, in English law, is the compulsory execution or carrying out of a contract in its details, the court of chancery generally having alone jurisdiction to enforce specific performance. In Scotland, the corresponding phrase is *implement*. As a general rule the courts do not attempt to enforce specific performance, but as a substitute give the party injured by the breach of contract satisfaction in the shape of damages.

SPECTACLES, for the purpose of aiding the sight when impaired by age or otherwise (see **SIGHT**, **DEFECTS OF**), were invented during the 13th century. The merit is attributed

by some to Alexander di Spina, a Florentine monk, and by others to Roger Bacon. At first they were exceedingly clumsy, both in the lenses themselves and also in their frames; and but little improvement took place in them until the beginning of this century, when light metal frames were introduced, instead of the cumbrous horn or tortoise-shell mountings, which are still occasionally seen, and have obtained the name of goggles. So skillful are the workmen of Wolverhampton, where they are chiefly made, in the manufacture of steel frames, that some of exquisite workmanship are now turned out, which, with their lenses complete, are under a quarter of an ounce in weight. They have consequently displaced gold, silver, and all other materials, when comfort and effectiveness are preferred to useless show combined with inconvenience. The lenses themselves are nearly always made of the best optical glass, and by the best makers are ground with extreme care. Many profess to be made of "pebbles," or rock-crystal; but lenses really made of that material are exceedingly rare, and have no real advantage over good glass.

SPECTER BAT, *Phyllostoma*, a genus of bats having two membranous crests on the nose, the one leaf-like, the other in the form of a horseshoe. This gives to their face that peculiar appearance from which they derive their popular as well as their scientific name. The species are numerous, and all natives of the West Indies and South America.

SPECTROPHONE and **PHOTOPHONE** or **RADIOPHONE**. The action of these instruments depends upon the phenomena of radiant energy which within a few years have been observed by different physicists, but whose practical results, if the time has arrived when the term may be used, have been principally accomplished by Prof. Alexander Graham Bell, the inventor of the speaking telephone in common use, in conjunction with Mr. Sumner Tainter. The invention of the photophone arose from the employment by Willoughby Smith of selenium as a resistance medium in testing submarine cables. It was found that the resistance of selenium to the galvanic current varied considerably, and the discovery was made that this was caused by the action of light, which lessened the resistance. When selenium is exposed to the action of the solar spectrum, the maximum effect is produced, according to Sale, just outside of the red end of the spectrum, in a point nearly coincident with the maximum of the heat rays (see *Radiation* in article **HEAT**), but according to Adams it is produced in the greenish-yellow or most luminous part of the spectrum, and he moreover found that selenium was sensitive to the cold light of the moon. E. W. Siemens discovered that heat and light produced opposite effects upon some extremely sensitive varieties of selenium. In some of his experiments the resistance on exposure to light was only one-fifteenth of what it was in the dark. It occurred to Prof. Bell to substitute the telephone for the galvanometer hitherto used in these experiments on account of its great sensitiveness to electrical influences; but in doing so it was necessary to vary the action of light so that the intermissions from light to darkness should be sudden, in order to produce a succession of changes in the conductivity of the selenium corresponding in frequency to the musical vibrations within the limits of hearing; and upon further consideration it appeared to him that all the audible effects obtained from varieties of electricity could also be produced by variations of light acting on selenium. In an article in *Science* of Sept. 11, 1880, he says: "I saw that the effect could be produced at the extreme distance at which selenium would respond to the action of a luminous body, but that this distance could be indefinitely increased by the use of a parallel beam of light, so that we could telephone from one place to another without the necessity of a conducting wire between the transmitter and receiver. It was evidently necessary, in order to reduce this idea to practice, to devise an apparatus to be operated on by the voice of the speaker, by which variations could be produced in a parallel beam of light, corresponding to the variations in the air produced by the voice." But a difficulty was found in the fact that the resistance of selenium was too great to respond sufficiently to the action of light; this, however, was overcome by reducing this resistance—from some half million *ohms* to 300 in the dark, and to 155 in the light. The fundamental features of the selenium photophone are best given in Prof. Bell's own words: "We have devised about fifty forms of apparatus for varying a beam of light in the manner required. The best and simplest form consists of a plain mirror of flexible material—such as silvered mica or microscopic glass. Against the back of this mirror the speaker's voice is directed. The light reflected from this mirror is thus thrown into vibration corresponding to those of the diaphragm itself. In arranging the apparatus for the purpose of reproducing sound at a distance any powerful source of light may be used, but we have experimented chiefly with sunlight. For this purpose a large beam is concentrated by means of a lens upon the diaphragm mirror, and after reflection is again rendered parallel by means of another lens. The beam is received at a distant station upon a parabolic reflector, in the focus of which is placed a sensitive selenium cell, connected in a local circuit with a battery and telephone." The loudest effects obtained from light were produced by rapidly interrupting the beam by a perforated rotating disk, revolving over the face of another perforated disk, with holes corresponding. Audible musical tones were produced from the light of a candle.

The experiments connected with the construction of this apparatus led to others with other substances than selenium, and also without the use of telephone or battery. A thin sheet of hard rubber was held close to the ear while a beam of intermittent light was thrown upon it by a lens, the result being the production of a musical note, and this

effect was intensified by arranging the hard rubber as a diaphragm and listening through a hearing-tube. The remarkable though natural conclusion was reached "*that sounds can be produced by the action of a variable light from substances of all kinds when in the form of thin diaphragms.*" Subsequently Prof. Bell arrived at the conclusion that *sonorousness under the influence of intermittent light is a property of all matter.* Various experiments were made with different fibrous and porous materials, such as cotton-wool, worsted, silks, sponge, lamp-black, etc. These articles were inclosed in a conical cavity, contained in a piece of brass, and closed by a flat plate of glass through which an intermittent beam of light was thrown upon them. A hearing-tube communicated with the cavity. Mr. Tainter found that the darkest shades produced the best effects. Black worsted especially gave an extremely loud sound. Cotton-wool darkened with lamp-black gave so loud a sound as to suggest the use of lamp-black alone. Of this substance a teaspoonful, placed in a test-tube and exposed to an intermittent beam of sunlight produced the loudest sound of all, and a piece of smoked glass, with the smoked surface receiving the intermittent beam, gave a fine effect. Upon smoking the interior of the conical cavity of the receiver above-mentioned, and then exposing it to the intermittent beam, "the effect was perfectly startling. The sound was so loud as to be actually painful to the ear placed closely against the end of the hearing-tube." The various experiments above alluded to will probably be of great importance in telephony as indicating that lamp-black may be substituted for selenium in an electrical receiver. M. Mercadier passed an intermittent beam from an electric lamp through a prism and found a difference in the audible effects in different parts of the spectrum. These experiments were repeated by Prof. Bell, with somewhat different results. Under conditions not necessary to describe here, "sounds were obtained in every part of the visible spectrum excepting the extreme half of the violet, as well as in the ultra-red. A continuous increase in the loudness of the sound was observed upon moving the receiver gradually from the violet into the ultra-red. The point of maximum sound lay very far out in the ultra-red, corresponding exactly with the proportion of heat in different parts of the spectrum, and showing that these effects are produced by the heat which accompanies light. Beyond this point the sound began to decrease, and then stopped so suddenly that a very slight motion of the receiver made all the difference between almost maximum sound and complete silence." Removing the smoked wire gauze from the receiver and substituting red worsted different results were obtained, the maximum effect being produced in the green at that part where the red worsted appeared to be black. On either side of this point the sound gradually died away. On substituting green silk for the red worsted the maximum effects were found in the red. A test tube containing the vapor of sulphuric ether was then substituted for the receiver, but no effects were observed till a certain point far out in the ultra-red was reached, when a musical tone was suddenly produced, which disappeared as suddenly farther on. With the vapor of iodine the maximum effect was in the green. These, and experiments with other substances, led to the conclusion that "the nature of the rays that produce sonorous effects in different substances depends upon the nature of the substances that are exposed to the beam, and that the sounds are in every case due to those rays of the spectrum that are absorbed by the body." These phenomena led Prof. Bell to the construction of a new instrument for use in spectrum analysis. "The eye-piece of a spectroscope is removed and sensitive substances are placed in the focal point of the instrument behind an opaque diaphragm containing a slit. These substances are put in communication with the ear by means of a hearing-tube, and thus the instrument is converted into a veritable 'spectrophone.' Suppose we smoke the interior of our spectrophonic receiver and fill the cavity with peroxide of nitrogen gas. We have then a combination that gives us good sounds in all parts of the spectrum, visible and invisible, except the ultra-violet. Now pass a rapidly interrupted beam of light through some substance whose absorption spectrum is to be investigated, and bands of sound and silence are observed upon exploring the spectrum, the silent positions corresponding to the absorption bands. Of course the ear cannot for one moment compete with the eye in the examination of the visible part of the spectrum; but in the invisible part beyond the red, where the eye is useless, the ear is invaluable. In working in this region of the spectrum, lamp-black alone may be used in the spectrophonic receiver. Indeed, the sounds produced by this substance in the ultra-red are so well marked as to constitute our instrument a most reliable and convenient substitute for the thermo-pile." See *Science* for May 28, 1881. Prof. Bell recognizes the fact that the spectrophone is only an adjunct to the spectroscope, but believes that it will have a wide and independent field of usefulness in the investigation of absorption spectra in the ultra-red. See **RADIOPHONY**.

SPECTROSCOPE, the instrument by the aid of which spectral phenomena (see **SPECTRUM**) may be most conveniently studied. It consists essentially of, first, a narrow slit, from which parallel rays of light proceed; secondly, a prism or train of prisms, to separate the differently refrangible rays; and thirdly, a telescope, to view a magnified image of the spectrum produced. See **SUN**.

SPECTRUM (Gr.) is a term applied in optics to the colored image of the sun or other luminous body, produced by refraction through a prism (q.v.), by diffraction (q.v.) through a fine grating, etc. In what follows we shall confine ourselves to the spectrum produced by a prism, as that which is commonly used. Besides, so far as we have at

present occasion to examine it, it presents very nearly the same appearance as spectra produced by other processes.

The solar spectrum was first carefully examined by Newton, who deduced from his observations the composite nature of white light, and the different refrangibilities of its various colored constituents. A ray of sunlight enters a darkened room through a small hole, in a shutter. It proceeds in a straight line to the opposite wall, and forms as a circular white spot, an image of the sun. If the edge of a glass prism be interposed in the path of this ray, the white spot disappears, and the spectrum is produced. In this form of experiment, its shape is that of a rectangle with semicircular ends.

The breadth of the spectrum is equal to the diameter of the spot; and it is brilliantly colored, the one end being red, and the other end violet. Between these we have gradations of color, and the whole appeared to Newton to be divisible into seven differently colored spaces, which he called red, orange, yellow, green, blue, indigo, violet. This was in accordance with the speculations of old days, when analogies were constantly looked for, and seems to have been suggested to Newton by the common musical scale. It is impossible, however, to settle precisely the exact boundary between any two of these fancied species of color; and, besides, such a description of the spectrum (though complete enough for mere popular language) is totally inadequate to express our present knowledge of the subject. In order to study the spectrum a little more closely, suppose we have pieces of colored glass which allow only one definite color to pass. With a red glass placed at the hole in the shutter, the prism being removed, the effect would be to render the spot red, without changing its position. Introduce the prism, and the effect is to change the position of the spot without altering its size or color.

Similarly, with a violet glass we have a violet spot, and so on; the change of position, due to refraction, being least for red and greatest for violet. It thus appears that the spectrum formed in this way, is made up of a series of circular spots, of the various colors of which white light consists all of the same size, and having their centers ranged along a line, so that each overlaps those next it. The only parts of the spectrum which are *pure*, i.e., where no two or more colors are mixed, are the ends; so that, by this process, it is impossible to separate definitely the rays of different refrangibility, so as to see, for instance, *whether any are wanting*. How, then, are we to ascertain whether sunlight contains rays of every refrangibility from red to violet? The obvious method is to make the spot not circular, but long and very narrow, a process mentioned by Newton himself. To make this spot thus narrow, a method commonly employed, is to set the prism about half-way between the shutter and the screen and to place before it a lens, such that, if the prism were removed, there would be an image of the hole in the shutter nearly equal to it in size. The hole must, therefore, be a narrow slit, parallel to the edge of the prism. When this arrangement is adjusted we have a pure spectrum, and we find it to be (at first sight) *continuous*. Thus, it appears that sunlight contains rays of every refrangibility, from the highest to the lowest; and that Newton's sevenfold division of it, though sometimes convenient for popular reference, has no scientific basis. Besides, what we can see is not the whole spectrum but a mere fraction of it; for beyond the red end, there are invisible rays recognized at once by their heating powers; and beyond the violet, there are invisible rays more powerful than the visible in producing chemical changes, as on a photographic plate, and which can be changed into visible rays by fluorescent substances. See PHOSPHORESCENCE. The breadth of the visible spectrum evidently depends on the *length* of the slit, its length on the difference of refrangibility of red and violet.

If we cut a narrow slit in the screen on which the spectrum falls, in a direction perpendicular to its length, the light which passes through has a definite refrangibility, and can no longer be drawn out by a prism into a spectrum. This experiment also is due to Newton.

If the slit in the shutter be very narrow, and the prism be adjusted to the most favorable position (so that the incident and refracted rays make equal angles with the surfaces on which they impinge, and from which they escape, respectively), we see that after all the solar spectrum is *not* continuous. It is found to be crossed at intervals by dark bands, showing the absence of rays of certain definite refrangibilities. The phenomenon is found to be the same whatever be the substance of the prism; so that these rays are really wanting in sunlight.

This important discovery was made by Wollaston, but the bands were first carefully observed and measured by Fraunhofer, from whom they are commonly called *Fraunhofer's lines*. We owe to Fraunhofer the invaluable suggestion of employing a telescope to examine the spectrum. The refracted rays are received directly on the object-glass of the telescope, which forms an image of the spectrum to be examined with the aid of the eye-piece, the screen being dispensed with. Wollaston had seen only five lines; Fraunhofer at once discovered four hundred; Brewster, with more perfect apparatus, counted two thousand; and now, with a train of prisms, and powerful telescopes, their number seems beyond computation. They show every variety of breadth and distinctness, and are grouped in the most irregular manner. For reference, Fraunhofer selected some of the more prominent, to which he attached the earlier letters of the alphabet. By their help he was enabled to measure refractory indices (see REFRACTION) with a precision

completely unlooked for. If the light of a candle, a bright gas-flame, a white-hot wire, or a lime-ball in the oxyhydrogen flame, be examined in the same way, *no such lines are seen*. But some of them, and others not apparently belonging to sunlight, were found by Fraunhofer in the spectra of various fixed stars—while the light of the moon and planets seemed to give spectra similar to that of sunlight.

The first to throw any light on this subject was Brewster. He showed that when light passed through nitrous acid gas its spectrum was interrupted by countless lines; and that they increased in number and breadth by the application of heat to the gas, so that at a high temperature a thin layer of this gas is *opaque to direct sunlight*. Hence it was natural to conclude that the dark bands in the solar spectrum are caused by absorption in some medium lying between us and the sun. It is to be observed, however, that this is on the supposition that light as it comes immediately from the sun would give, like that of the lime ball, a continuous spectrum. But Brewster went further. He showed that *some* of Fraunhofer's lines depend on the altitude of the sun, that is, on the greater or less space of air, fog, and vapor through which his rays must pass before reaching the earth. *Some of them, then, are caused by absorption in the earth's atmosphere.*

But we must now look to another class of phenomena. A spirit lamp flame gives a very feeble spectrum; and, if a little common salt be put on the wick, although the flame becomes instantly very much brighter, no alteration is produced on the spectrum, save the appearance of a *bright* yellow line, crossing it at the place where the dark line called by Fraunhofer D appears in sunlight. On examining this line carefully Fraunhofer found that it, like D, is double—and he verified that these two rays were exactly (so far as refractive index goes) two of those wanting in sunlight, and in the light of some of the stars.

About the same time Talbot and Herschel (q.v.) showed that the colors given by Lithia, Strontia, etc., in a spirit flame were, like that produced by common salt, due to the production of light of several perfectly definite refrangibilities; so that the spectrum of the lamp-flame was crossed in each case by a series of bright lines always the same when the same body was placed in the flame; and they suggested (in 1825) the application of this method to the qualitative analysis of minerals, etc., when the presence of extremely minute quantities of different bodies has to be ascertained. This was, in reality, the foundation of SPECTRUM ANALYSIS; and the method was, we may say, almost complete, so far as practice is concerned. The theory, however, was left incomplete, so far as regards the cause of dark lines in the solar spectrum. Foucault (in 1849) seems to have been the first to approach the true explanation. An experiment of his, from which, however, he drew no inferences, contains the complete theory. When salt is placed in the voltaic arc (see ELECTRIC LIGHTING) the spectrum gives the double bright line (coinciding with the double dark line D) already referred to. When sunlight passes through this arc its dark line D is *strengthened*, instead of being filled up by the yellow light from the arc as we might have expected; and when one of the white-hot carbon-points (which gives a continuous spectrum) is looked at through the yellow arc, the double dark line D appears in its spectrum.

Stokes learning, in 1850, that experiments had been made by Professor Miller of Cambridge, to test with great accuracy Fraunhofer's assertion as to the exact coincidence of the double bright line of a salted flame with the double dark line of the solar spectrum, gave for the first time the physical explanation of the phenomenon. He compared the salt-flame to a space full of tuning-forks or piano-forte wires all tuned to the same note. When they are in vibration they, of course, give out this note—similarly the salt-flame the *bright* lines. When, however, sounds are produced in their neighborhood, as they naturally vibrate to one definite note, they will be set in vibration by it (i.e., will absorb it) if it be part of the sound.—Thus sound which has passed through such a space has had this note eliminated from it—similarly the salt flame seizes these yellow rays from white light passing through it. This ingenious and satisfactory explanation shows at once that the line D proves the existence of salt (or sodium) in the atmosphere of the sun. Stokes's theory was not published, except in so far as it was annually given by sir W. Thompson (q.v.) in his lectures in Glasgow—so that it was independently discovered, or all but discovered, by various other philosophers some 8 or 10 years later. The earliest of these was Balfour Stewart of the Kew observatory, who proved by reasoning and experiment that a body's absorbing power for any ray of light or heat is equal to its radiating power for the same. Angström all but made the rediscovery. Finally Kirchhoff, by reasoning similar to that of Stewart, and by actually reversing the spectra of certain substances, arrived at the same results; and, in conjunction with Bunsen, applied them to chemical analysis, with the immediate result of discovering two new metals.

One of the most valuable parts of Kirchhoff's investigation is his map of the solar spectrum with its dark lines; side by side with which is a spectrum containing the bright lines given by various metals volatilized in an electric spark. The sunlight is admitted through the upper half of the slit, the light from the burning metal through the lower—and thus the two are subject to precisely the same deflections by the train of prisms.

When there is much moisture in the atmosphere, the solar spectrum shows what is called the *rain-band*. Huggins showed that the spectra of planetary nebulae, and of the

tails of comets, consist of a few *bright* lines only—indicating that these bodies—or, at all events, those portions of them from which their light proceeds—are masses of incandescent vapors or gases.

Again, Stokes has traced, by the alteration of the absorption bands produced by the coloring matter of blood, the oxidation and reduction which constantly take place in this substance, and its connection with the distinction between venous and arterial blood. See Roscoe's *Spectrum Analysis*.

SPECULUM METAL, an alloy of copper and tin, used for making the reflecting surfaces of reflecting telescopes. The best consists of 126.4 parts copper to 58.9 tin. To obtain a perfect alloy, and to cast it successfully, is a matter of great difficulty, requiring much skill and experience. See TELESCOPE.

SPEDDING, JAMES (1808–81), an English scholar, born in Cumberland, Eng. He graduated at, and became honorary fellow of, Trinity college, Cambridge. His life was devoted to the study of Francis Bacon. With R. L. Ellis and D. D. Heath he published (1857–9) the edition of Bacon's works which bears his name, and in 1870 commenced the publication of a *Life and Letters of Francis Bacon*. He published also *Publishers and Authors* (1867); *Reviews and Discussions* (1869), and *Life and Times of Francis Bacon* (1878).

SPEEDWELL, *Veronica*, a genus of plants of the natural order *scrophulariaceæ*, distinguished by a 4-cleft wheel-shaped corolla, with the lower segment narrower, two stamens, and a two-celled capsule. The species are very numerous, annual and perennial herbaceous plants and small shrubs, natives of temperate and cold climates in all parts of the globe. Some of them grow in wet ditches and in marshes, some only on the driest soils. They have generally very beautiful blue, white, or pink flowers. The number of British species is considerable, and few wild-flowers are more beautiful than the germander speedwell (*V. chamædrys*), or the alpine species, *V. alpina* and *V. saxatilis*. A number of species are very generally cultivated in flower-gardens.—The bitter and astringent leaves of the COMMON SPEEDWELL (*V. officinalis*), one of the most abundant British species, found also in almost all the northern parts of the world, are in some countries used as a tonic, sudorific, diuretic, and expectorant medicine. They are also employed, particularly in Sweden, as a substitute for tea; as are those of the germander speedwell.—*V. virginica* is called *Culver's physic* in North America; it is said to be actively diuretic, and a decoction of the fresh root is violently cathartic and emetic.—Brooklime (q.v.) belongs to this genus.

SPEISS, a residue found in the bottoms of crucibles in which smalts or cobalt glass has been melted. It consists of nickel, arsenic, sulphur, with traces of cobalt, copper, and antimony.

SPEKE, JOHN HANNING, an African traveler, was born near Bideford, Devonshire, in May, 1827; was educated at the Barnstaple grammar-school, and at the age of 17 went to India. He entered the native Bengal infantry as a cadet, and saw much service during the war in the Punjab. A keen sportsman, with a taste for natural history, he employed his rifle with success in collecting for the museums specimens of the rarer mammals and birds of India, and with this view he undertook several exploratory trips into the Himalayas. It was while so employed that he first conceived the idea of becoming an African traveler. The English government had resolved, in 1854, to dispatch an expedition from Aden into the neighboring region of Africa, under the command of capt. Burton (q.v.). Speke, then a lieut. in the Indian army, reached Aden at this time, on leave of absence, and resolved to join Burton and his companions, lieuts. Herne and Stroyan. Burton went to Harar; and Speke was detached to visit the Dalbahantas, the most warlike of the Somaui tribes. On the return of the travelers to their starting-point on the coast, they were attacked by 150 men. Stroyan was killed, and Speke made a narrow escape with 11 wounds. The attention of the geographical society of London had now been called to the subject of the great lakes of tropical Africa; and in June, 1857, they dispatched Burton and Speke. These travelers entered the country from Zanguebar, as the German missionaries Krapf and Rebmann had done in 1847, and discovered the great lake Tanganyika. The details of their discoveries till they reached Gondokoro, in Mar., 1863, are given in the article NILE. On Sept. 15, 1864, Speke was killed by a gun-accident while out shooting in the neighborhood of Bath.—Speke is the author of a *Journal of the Discovery of the Source of the Nile*, and *What led to the Discovery of the Source of the Nile*.

SPELLING REFORM. In respect of orthography English is the most abnormal of tongues (see PHONETIC WRITING). No one on seeing a word for the first time knows how to pronounce it, or, on hearing it, how to write it. Children cannot learn to read or spell without wasting years that ought to be given to acquiring knowledge. Our spelling, originally phonetic, became corrupted, (1) by retaining letters that have become silent; as in *know*, *psalm*; (2) by having the same symbol for divergent or dissimilar sounds, as a in *ale*, *add*, *arm*, *ask*, *all*, *what*; *ough* in *cough*, *dough*, *through*, *plough*, *enough*, *hiccough* and Scottish *sough*; (3) different symbols for sounds that have converged; as in *name*, *fail*, *weight*, *great*.

Many isolated efforts have been made to remedy this. At length the subject has

attracted the notice of our foremost philologists, as Ellis, March, Murray, Whitney, Müller, Sweet, etc., and the English and American Spelling Reform associations are the result. In 1881 the English Philological assoc. proposed certain corrections which have been generally approved by the American assoc. We summarize the principal.

Drop silent letters where phonetically or etymologically useless, as *e* from *are*, *come*, *assemble*, *medicine*, *driven*, *barred*, *heart*, *yeoman*; *a* from *breast*, *beat*, *beauty*; *o* from *jeopardy*, *country*; *i* from *parliament*; *u* from *honour*, *guess*, *bought*; *ue* from *catalogue*, *tongue*; *b* from *limb*, *thumb*; *c* from *scent*, *scythe*; *h* from *aghast*, *ghost*; *l* from *could*; *s* from *island*; *t* from *witch*; *w* from *whole*. For *centre*, *theatre*, write *center*, *theater*; for *expence*, *defence*, *pence*, *expens*, *defens*. *pens*; change participial *ed* into *t* after unvoiced consonants, as *missed*, *mist*; *looked*, *lookt*: Substitute *f* for *gh* in *draught*, *cough*, and for *ph* in *philosophy sphere*; *z* for *s* in *risen* (*rizen*). Do not double final *b*, *d*, *g*, *n*, *r*, *t* after short vowels, nor *f*, *l*, *z* where unnecessary. Respell abnormal words as *phthisical* (*tizikal*), *comptroller* (*kontroler*), *tongue* (*tung*).

The objection to this reform, that it is unetymological, is met by the allegation that it is urged by the foremost etymologists of the age, and the doubts regarding its practicability are met by the examples of similar reforms having been successfully carried out in ancient Greece and in Holland and Spain. The partial and conservative change advocated would still, however, cause the justly dreaded confusion. The essential to its success is that it be adopted in our school-books and gradually by the press, and this will probably not occur.

SPELMAN, Sir HENRY, 1562-1641; b. England; studied at Trinity college, Cambridge; studied law at Lincoln's inn; was knighted by James I.; retired to London in 1612 to devote himself to antiquarian research; published in 1626 the first part of *Glossarium Archæologicum*; next, an edition of *English Councils*. His *Treatise Concerning Tithes* and *History of Sacrilege*, are valuable. His posthumous works were issued at Oxford in 1698 under the title *Reliquiæ Spelmannianæ*.

SPELT. See WHEAT.

SPELTER. See ZINC.

SPENCE, JOSEPH, 1699-1768; b. England; educated at Oxford; fellow, 1722; ordained, 1728; became rector of Birchanger, Essex, and professor of poetry in the college; traveled, 1730-33, in France and Italy; re-elected, while absent, professor of poetry; traveled again, 1739-42; rector of Great Horwood and professor of modern history at Oxford; prebend of Durham cathedral, 1754. His publications are *Polymetis*; *Anecdotes*, *Observations*, and *Characteristics of Books and Men*; *Essay on Pope's Translation of Homer*.

SPENCER, a co. in s.w. Indiana, bounded on the s.e. and s.w. by the Ohio river, crossed by the Louisville, Evansville, and St. Louis railroad; about 390 sq. m.; pop. '90, 22,060. Co. seat, Rockport.

SPENCER, a co. in n. Kentucky, drained by the Salt fork of the Ohio river and Clear creek, the former bounding it on the n.e.; 200 sq. m.; pop. '90, 6760, chiefly of American birth. Co. seat, Taylorsville.

SPENCER, a town in Worcester co., Mass.; on the Boston and Albany railroad; 12 miles w. of Worcester. It was incorporated in 1753; contains several villages; and has the David Prouty high school, the Richard Sugden public library, Spencer public park, electric lights and street railroads, and manufactories of boots, shoes, wire, woolen goods, and satinet. Pop. '90, 8747.

SPENCER, AMBROSE, LL.D., 1765-1848; b. Conn.; educated at Yale and Harvard, and called to the bar. He settled in the state of New York, and was a member of both branches of its legislature. He was attorney-general of the state, 1802-4; associate justice of the state supreme court, of which he was chief justice, 1819-23. He was subsequently member of congress and mayor of Albany.

SPENCER, GEORGE ELIPHAZ, b. Jefferson co., N. Y., 1836; was educated at Montreal college, Canada; was admitted to the Iowa bar, 1856. He was secretary of the Iowa senate, 1858. He entered the union army as capt., 1862; commanded a brigade of cavalry on Sherman's march to the sea, and was brevetted brig.-gen. for gallantry; settled in Alabama, 1865, and was elected U. S. senator, as a repub., 1868, and re-elected, 1872. He aided in the exposure of the star-route frauds, and advanced the legislation leading to the reduction of letter postage to two cents. In 1881 became commissioner of the Union Pacific railroad.

SPENCER, GEORGE JOHN, D.C.L., 2d Earl, 1758-1834; b. England; succeeded to the title in 1821. He was 1st lord of the admiralty, 1794-1801, and afterward home secretary. His private library was one of the best in Europe.

SPENCER, HERBERT, English scientist, b. in Derby in 1820. He was educated by his father, W. G. Spencer, a teacher, chiefly of mathematics, and his uncle, the rev. Thomas Spencer, a clergyman of the established church, well known for his liberal opinions on political and ecclesiastical questions. At the age of 17 he became a civil engineer; but after about 8 years abandoned the profession, in consequence of the large influx of young men brought into it during the railway mania, and the consequent undue competition. During the 8 years of his engineering life he contributed various papers to the *Civil Engineers' and Architects' Journal*. His first productions in general

literature were in the shape of a series of letters on the "Proper Sphere of Government," published in the *Nonconformist* newspaper in 1842, which were some time after reprinted as a pamphlet. From the close of 1848 to the middle of 1853 he was engaged on the *Economist*, then edited by the late James Wilson, M. P.; and during this time he published his first considerable work, *Social Statics*. Shortly afterward he began to write for the quarterly reviews, most of his articles appearing in the *Westminster*, and others in the *North British*, *British Quarterly*, *Edinburgh*, *Medico-chirurgical*, etc. In 1855 appeared his *Principles of Psychology*. In 1860 he commenced a connected series of philosophical works, designed to unfold in their natural order the principles of biology, psychology, sociology, and morality. To this series belong, besides the *Psychology* (2 vols., new ed. 1871-72), *First Principles* (1862, 2d. ed. 1867); *Principles of Biology* (1864); *Principles of Sociology* (parts 1 to 4, 1876-80); and *The Data of Ethics* (part of *Principles of Ethics*, 1879). *Education* was published in 1861; *The Study of Sociology* in 1872; and *Descriptive Sociology* in 1873-78; *Negative Beneficence and Positive Beneficence* (1893); *Rejoinder to Professor Weissmann* (1894); *Weissmann Once More* (1895). The last volume of the *Principles of Sociology*, completing the scheme of the great philosophical work which he had set himself, appeared in Nov., 1896. Spencer has developed and applied universally the theory of evolution, and of late years has published *Ceremonial Institutions* (1879); *Political Institutions* (1882); *Ecclesiastical Institutions* (1885), these being parts of the *Principles of Sociology*; *Essays: Scientific, Political and Speculative* (4 vols.); *The Insuperable Book*, etc. He visited the U. S., 1882, but at his own earnestly expressed desire was suffered to make the tour of the principal American cities with comparative immunity from the newspaper reporter, and lion-hunter. In 1883, May 12, he was elected a correspondent of the French acad. of moral and political sciences for the section of philosophy, filling the place left vacant by the death of Ralph Waldo Emerson. In 1884 he was engaged in a controversy with Frederic Harrison, in the pages of the *Contemporary Review*, on the personality of God and the nature of religion. The publication of these essays in book form in the U. S., 1885, threatened at one time to bring about a personal rupture between S. and Harrison, who claimed that his rights in the joint authorship of the essays had been violated, but Mr. S.'s explanation was accepted as satisfactory.

S. has attempted to work out a complete system of philosophy in harmony with the principles and results of modern science. His philosophy is essentially speculative or deductive. It does not begin with observation and experiment, and rise through them to scientific generalizations. It starts with certain truths supposed to be ultimate, the test in all cases being the mental inconceivability of the opposite of the proposition; and seeks to explain phenomena from this assumed standpoint. He accepts the doctrine of relativity, which Hamilton and Mansel deduced from Kant, but carries it a step further. Though we can have definite consciousness of things only in their relation to each other, not as they are themselves—that is, of the relative and not of the absolute—such definite consciousness implies an indefinite consciousness of an absolute existence. In the recognition of this as inscrutable, science and religion find their reconciliation. Now, the manifestations of this unknowable power constitute what have just been called things in their relation to each other, of which we can have definite consciousness or knowledge: knowledge completely unified is philosophy. The data of philosophy are necessarily those organized components of our intelligence without which philosophizing could not go on. "Our postulates are: an unknowable power; the existence of knowable likenesses and differences among the manifestations of that power; and a resulting segregation of the manifestations into those of subject and object." Within each segregated mass there are likenesses and differences involving secondary segregations. The modes of cohesion under which manifestations are invariably presented are called, when contemplated apart, space and time; when contemplated with their manifestations, matter and motion. All these are traceable to experiences of that mode of consciousness whose reality is shown by its persistence—to force. By the "persistence of force" is meant the unchanging quantity, both of that mode of force which is revealed to us only by opposition to our own powers, and is not a worker of change, and of that mode which is a worker of change, actual or potential, and is specifically called energy. The persistence of force—that is, the persistence of some cause which transcends our knowledge and conception—is the truth which all other truths imply, and from which they all (including the law of evolution) are derived. From the fact that force can neither arise out of nor lapse into nothing, follows the uniformity of law. Force never disappears, it is only transformed. Motion follows the line of least resistance, and is perpetually reversed within limits—is rhythmical. So far of the factors of phenomena. The phenomena themselves must be under a law of the concomitant redistribution of matter and motion, which holds of every change. The law of the entire cycle of changes passed through by every existence is loss of motion and consequent integration, *i. e.*, evolution, eventually followed by gain of motion and consequent disintegration, *i. e.*, dissolution. In its complete shape the "formula of evolution" is thus stated: "Evolution is an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite, incoherent homogeneity to a definite coherent heterogeneity; and dur-

ing which the retained motion undergoes a parallel transformation." This law of evolution applies equally to all orders of phenomena—whether "astronomic, geologic, biologic, psychologic, etc."—since these all are component parts of one cosmos, though distinguished from one another by conventional groupings.

To the uniformity of law is due the genesis of our own ideas and the growth of our knowledge. The succession or co-existence of external phenomena produces a like succession or co-existence in our mental perceptions, and when any two physical states often occur together there is at length established an internal tendency for these states always to occur in the same order. All mental states—including those primary scientific ideas, the perceptions of matter, motion, space, and time—can be analyzed into a primitive element of consciousness, something which can be defined only as analogous to a nervous shock. These perceptions have now become innate in the individual. They may be called—as Kant called space and time—forms of intuition, but they have been acquired empirically by the race, through the persistence in the order or relationship of events in the environment, and from the accumulated experiences of each individual being transmitted in the form of modified structure to his descendants. From the lower phenomena of reflex action and instinct our unconscious life gradually merges in a succession of conscious phenomena, and we are borne upward through the regions of memory to the highest exercise of reason and normal development of feelings. The principles of morality are looked on by S. as the keystone of his system, all his other investigations being only preliminary to them. Ethics, he holds, has its root in physical, biological, psychological, and social phenomena, for by them the conditions of human activity are prescribed and supplied. The best conduct is that which most fully realizes evolution—which promotes the greatest totality of life in self, offspring, and fellow-men—the balance of egoism and altruism being attained by a compromise between these contending principles. The measure of life is said to be pleasure, but the utilitarian school are at fault in assuming that the end (greatest happiness) is better known than the means to it (morality); and for ignoring the fact, that accumulated experiences of utility have become consolidated in the race into a moral sense.

In the above summary, it has been impossible to give any idea of either the strength or weakness of the proof by which this elaborate system is supported. In general it may be said that its strength lies in the author's brilliant powers of generalization, his acquaintance with various departments of science, and his unsurpassed wealth of illustration. But a clear analysis of the notions which he employs is often wanting. Hence the unsatisfactoriness of the distinction between definite consciousness or knowledge, and the indefinite consciousness implied by it, which is not knowledge; the want of any proved relation between his objective and subjective aspects of psychology, the implicit assumption at the outset of the perception of space, etc., when the attempt is being made to show how they have been gradually produced in the mind by the action of the environment. Thus, too, in the *Sociology* the ethnographical method is followed to the exclusion of the more scientific historical method; and in the *Data of Ethics*, the compromise between egoism and altruism is left wholly indeterminate.

The wide knowledge which all S.'s writings display of physical science, and his constant endeavor to illustrate and support his system by connecting its position with scientific facts and laws, have given his philosophy great currency among men of science—more so, indeed, than among philosophical experts. At the same time, not only have the development and application that he has given to the theory of evolution profoundly affected contemporary speculation, but also he must be regarded as one of the few in history who have carried out the attempt to give a systematic account of the universe in its totality.

SPENCER, ICHABOD SMITH, D.D., 1798-1854; b. Vt.; graduated at Union college, 1822; studied theology with Prof. Yates; taught at Schenectady and Canandaigua; settled 1828, as colleague of the Rev. Solomon Williams, Northampton, Mass.; pastor of Second Presbyterian church, Brooklyn, N. Y., 1832; was professor extraordinary of biblical history in Union seminary, 1836-40; was invited to the presidency of the university of Alabama, 1830, of Hamilton college, 1832, professorship of pastoral theology, East Windsor seminary, 1853, and received calls from important churches, but declined all. He published *Pastor's Sketches*, 2 vols., and after his death appeared *Sacramental Discourses; Sermons; Evidences of Divine Revelation*. He was a man of positive character, of clear theological views, and great pastoral fidelity and success.

SPENCER, JESSE AMES, D.D., b. N. Y., 1816; graduated at Columbia college, 1837; studied theology at General theological seminary; ordained, 1840; rector of St. James's church, Goshen, N. Y.; traveled in Europe, 1842; visited Egypt and Palestine, 1848-49; professor of Latin and oriental languages at Burlington college, N. J., 1849-50; editor and secretary of the Episcopal Sunday-school union and church book society, 1851-57; rector of St. Paul's, Flatbush, L. I., 1863-65; professor of Greek in college of city of New York, 1869. He has published *Discourses; History of English Reformation; The New Testament in Greek, with Notes; Egypt and the Holy Land; History of United States*, 4 vols.

SPENCER, JOHN, D.D., an English theologian and scholar, was born in 1630 and became Dean of Ely. He was the author of a work on the laws and of the Hebrew ritual, written in Latin. He died in 1695.

SPENCER, JOHN CANFIELD, LL.D., 1788-1855; b. Hudson, N. Y.; son of chief-justice Ambrose Spencer; graduate of Union college, 1806; private secretary to gov. Tompkins, 1807. He studied law and commenced practice in Canandaigua, but removed to Albany, 1845; master in chancery, 1811. In 1813 he was on duty at the frontier as brigade judge-advocate; in 1814 postmaster of Canandaigua; in 1815 assistant attorney-general for w. New York; member congress, 1817-19. He was for some years member of the assembly or in the state senate. An anti-mason, he was government prosecutor against the supposed abductors of Morgan. In 1839-41 he was secretary of state; U. S. secretary of war under president Tyler; secretary of the treasury, 1843; resigned 1844 and resumed private practice. He was a zealous promoter of common-school education and all charitable objects. He edited the first American edition of De Tocqueville's *Democracy in America*.

SPENCER, JOHN CHARLES, Earl, English minister and statesman, son of the second earl, was b. in 1782. The founder of the family of the Spencers was the hon. John Spencer, youngest son of the third earl of Sunderland, by Anne, daughter and co-heiress of the great duke of Marlborough, and who inherited much property from his grandmother, Sarah, duchess of Marlborough. His only son was made earl Spencer in 1765.—The second earl was first lord of the admiralty under Mr. Pitt's administration—1794 to 1801—the period of the great naval victories of Camperdown, cape St. Vincent, and the Nile. He retired when Mr. Addington became premier, and became distinguished as a munificent collector of rare books. He was also first president of the Roxburghe club for reprinting rare and curious tracts.—The third earl, the subject of this notice—better known under the courtesy title of lord Althorp—was educated at Harrow school, and afterward at Trinity college, Cambridge. He entered parliament in 1804 as member for Oakhampton. In 1806 his father took office as secretary of state for the home department in the Grenville-Fox ministry, and Spencer became a junior lord of the treasury. He was returned for Northamptonshire, which he represented from 1806 until the period of the reform bill. In the reformed parliament he sat for the southern division of the county. He went out with the whigs in 1807, and during the long interval of their exclusion from office, steadily opposed the measures of the tory government. On the dissolution of the Wellington cabinet in Nov., 1830, he was appointed chancellor of the exchequer and leader of the house of commons in the celebrated reform ministry of earl Grey. The reform bill was introduced by lord J. Russell (q.v.), but the task of carrying the bill mainly devolved upon Spencer. In 1833 he brought in and carried the ministerial bill for reforming the Irish church. In this memorable working session, the curious statistician discovered that Spencer, who had, from his post of ministerial leader, naturally been the most frequent speaker, had addressed the house 1026 times, his speeches occupying 387 columns in the then *Mirror of Parliament*. In 1834 he introduced and obtained the assent of the legislature to the poor-law amendment act. When the Irish coercion bill was under consideration in the cabinet, Spencer had opposed the clauses prohibiting public meetings, yet had given way rather than break up the ministry; but when the truth was elicited in debate by Mr. O'Connell, Spencer resigned. He was considered and described by earl Grey as his "right-hand man," and without his assistance the earl felt himself unable to carry on the government. The administration of viscount Melbourne succeeded (July, 1834), in which Spencer consented to resume his office. In November he was called by the death of his father to the house of peers, which had the effect of bringing the Melbourne (q.v.) administration to an end. When the attempt of sir R. Peel to carry on the government failed, Spencer declined to take office again. He devoted his time to agricultural pursuits, became president of the Smithfield Cattle club, and suggested the formation of the royal agricultural society, of which he was elected president in 1838. He died at his seat, Wiseton hall, Notts, Oct. 1, 1845, without issue, and was succeeded by his brother. During his political career, his simplicity of character and integrity of purpose obtained for him the appellation of "honest lord Althorp." He was very little of an orator, but he had a clear and practical intellect, and his influence over the reformed house of commons was supreme. Lord Brougham dedicated to him his work on *Natural Theology*; and his *Dialogues on Instinct* are also supposed to be carried on with Spencer, to whose cultivation of philosophy in the midst of his political and agricultural pursuits, the author bears friendly testimony. See *Memoir* by sir Denis le Marchant, Bart. (London, 1876).

SPENCER, JOHN POYNTZ, fourth Earl Spencer, was born in England in 1835, educated at Cambridge, lord lieutenant of Ireland 1869-74 and again in 1882-85; and lord president of the council, with a seat in Mr. Gladstone's cabinet 1880-3 and 1885-6, first lord of admiralty 1892-5.

SPENCER, JOSEPH, 1714-89; b. Conn.; was judge of probate, 1753; joined the northern army, 1758, as maj. under Col. Whiting; was a member of the council, 1766, brig.gen. in continental army, 1775; maj.gen., 1776; was with the army in the expedition against Rhode Island, 1778; assisted in Sullivan's retreat; elected to congress, 1779 again elected to the council, 1780. He was greatly esteemed by Washington.

SPENCER GULF, a very large inlet on the coast of s. Australia (q.v.), between Eyria and Yorke peninsulas. It is about 209 m. in length, by 100 m. in greatest breadth.

SPENCER RIFLE. The principal characteristic of this arm is a magazine in the butt of the stock which holds seven cartridges, and from which the chamber is supplied by a movement of the trigger-guard. This acts as a lever, expelling the shell of the exploded cartridge, while it replaces it by a fresh one. The magazine when emptied is exchanged for a full one; or, by a simple movement, it can be shut off altogether, and the rifle made a single breech-loader. This rifle, which is described as a "breech-loading magazine gun," was generally used by the union cavalry during the war of 1861-65. See *illus.*, GUNS, vol. VII.

SPENER, PHILIPP JAKOB, a German reformer, and the founder of the sect known as *Pietists*, was born at Rappoltsweller (Fr. Ribeauville), in Upper Alsace, Jan. 25, 1635. His father was legal adviser to the Count von Rappoltsweller. At an early age Spener showed deep religious susceptibilities. After studying the classics at Colmar, he betook himself in 1651 to Strasburg, where the professors Dannhauer and Seb. Schmidt inspired him with a profound love of the Scriptures, not as a heap of dry theological bones, but as a fountain of life and spiritual thought. From 1659 to 1662 he attended the universities of Basel, Tübingen, Freiburg, Geneva, and Lyons. In the following year he became a preacher at Strasburg, where the unction of his sermons exercised a powerful influence on his hearers. At the age of 31 he was transferred to Frankfurt as first pastor; and here, as elsewhere, the profound spiritualism of the man, springing out of a free, simple, *untheological* faith in the Bible, made itself apparent in his preaching and life. Yet Spener was the very opposite of what is commonly called a *mystic*. The devotions which he sought to excite were not to show themselves in transcendental ecstasies, amid which common sense is apt to swoon away, but in acts of piety, humility, and charity. The "Sermon on the Mount" was the medium through which he gazed upon the "truth as it is in Jesus." He had a strong aversion to what goes by the name of theology, which he considered a hateful caricature of the free word of life; and he commenced in the year 1670, at his house, meetings for the cultivation of evangelical morality. These were the famous *collegia pietatis*, whose influence for good on the German character, in those days of stony and barren orthodoxy, cannot easily be overvalued. At the same time he took pains to reorganize the method of catechising, and to improve the religious instruction given to children. His conduct in all this was marked by such prudence and discernment, that he long escaped the animadversions of the "high and dry" Lutherans; but in 1679, a preface which he wrote for a new edition of the *Postille* of Arndt, in which he censured the morals of the upper classes, made him the target for their envenomed shafts; and after some years, he was fain to accept the invitation to become court-preacher at Dresden, and member of the upper consistory. In this capacity he effected important ameliorations in the theological teaching of the university of Leipsic, and in the system of religious catechising practiced throughout Saxony; but in 1689 he fell into disgrace for having addressed a temperate but energetic remonstrance to the elector Johann Georg III. on the subject of his personal vices, was attacked by Carpzow, who coveted his place at court, and by other orthodox theologians, and in 1691 went to Berlin as provost of the church of St. Nicholas, and consistorial inspector, offices which he retained to the end of his life. The elector of Brandenburg encouraged his efforts after religious reform, and intrusted theological instruction in the new university of Halle to Franke, Breithaupt, and other disciples of Spener—a matter that excited great irritation in the theological faculties of Wittenberg and Leipsic, which had formally censured as heretical no less than 264 propositions drawn from Spener's writings. Spener died at Berlin, Feb. 5, 1705, leaving behind him a reputation for piety, wisdom, and practical Christian energy, which all the excesses of the later pietists have not obscured. His writings are numerous; the chief are *Pia Desideria* (Frankf. 1675), *Das geistliche Priesterthum* (Frankf. 1677), *Christliche Leichenpredigten* (13 vols., Frankf. 1677), *Des thätigen Christenthums Nothwendigkeit* (Frankf. 1679), *Klagen über das verdorbene Christenthum* (Frankf. 1684), *Evangelische Glaubenslehre* (Frankf. 1688), and *Theologische Bedenken* (Halle, 5 vols., 1700-21). See Hossbach's *Phil. Jak. Spener und seiner Zeit* (2 vols., Berl. 1828); Thilo's *Spener als Katechet* (Stutt. 1841); and Wildenhalm's *Phil. Jak. Spener* (Leip. 1842-47).

SPENSER, EDMUND, one of the chief literary ornaments of the great Elizabethan period, was born in London in the year 1552. There is some ground for supposing him to have been of good family connection; but inasmuch as of neither of his parents is anything whatever known, the evidence of this is precarious. In 1569 he went to Pembroke Hall, Cambridge, in the humble capacity of sizar, in itself a sufficient proof that whatever his family, the gifts of fortune were deficient. At Cambridge he remained several years, becoming bachelor of arts in 1572, and master in 1576. After leaving college, he went to live with friends in the n. of England. Of the detail of his life at this period, nothing is known further than that he busied himself with poetry, his first volume of which, *The Shepheard's Calendar*, was published in 1579. Its dedication to sir Philip Sidney was the means of introducing him to that noble and kindly gentleman, who not only extended to him a generous patronage, but honored him with his warm friendship. He seems for some time to have been domesticated with sir Philip at Leicester house, from which he dates his moiety of the *Four Epistles*, exchanged be-

tween him and Gabriel Harvey, and printed in 1580. Toward the end of this year, through the influence of Sidney's uncle, the earl of Leicester, an appointment was procured for him as secretary to lord Grey of Wilton, the queen's deputy in Ireland, whither he at once proceeded. About this time it was that he commenced his great work, *The Faery Queen*. His official duties must have been punctually and ably performed, as in 1586 we find his services rewarded by a grant from the crown of Kilcolman in the county of Cork, an estate of upward of 3,000 acres, on which he now went to reside. Along with this piece of good fortune came the evil news to him of the death of his friend Sidney at Zutphen, an event which he musically bewails in the elegy entitled *Astrophel*. Subsequently the place of Sidney, as at once his patron and friend, was in a measure supplied by sir Walter Raleigh, who visited him in Ireland in 1590, took him along with him to England, and introduced him to the notice of queen Elizabeth. His experiences as a suitor for court-favor seem not to have been specially of a pleasant kind, if we may judge from a passage in one of his works, in which a keen personal feeling of wrong and weary humiliation speaks out unmistakably. Documentary evidence exists, however, that a pension of £50 per annum was granted him by queen Elizabeth; that it was ever paid, or paid with due punctuality, there seems considerable reason to doubt. That Elizabeth, along with her greater qualities, could exhibit on occasion an extreme meanness and stinginess, there is no reason to doubt whatever. What portion of Spenser's after-life was passed in England, what in Ireland, we do not distinctly know. Nearly all we distinctly know of him henceforth is the date of his several publications. The first three books of *The Faery Queen*, issued on his arrival in England in 1590, were followed the year after by three more, and a collection of lesser pieces entitled *Complaints*, including *Mother Hubbard's Tale*, the *Tears of the Muses*, etc.; and in 1596 by four *Hymns*, so called, in which the Platonic doctrine of beauty is elaborated in noble music. In 1596 he wrote his *View of Ireland*, a treatise full of sagacious observation and remark, which was only published long after in Dublin in 1633. Further than this, all record which survives to us of Spenser is summed in the facts that in 1594 he was married to a woman whose very name has perished; that in 1598 he was made sheriff of Cork by the queen; and that in the course of the same year the deplorable calamity befell him which shortly preceded and in part may have caused his death. Tyrone's rebellion having broken out, his house at Kilcolman was sacked and burned by the rebels, he and his wife with difficulty escaping, while their youngest child perished in the flames. On Jan. 15, 1599, his death took place in London. According to the account given by Ben Jonson to Drummond, he "*died for lack of bread.*" This is not likely to have been in the literal sense true, but it is scarce possible to evade the inference from it, as coming from one so likely to be well informed as Jonson, of a state of great wretchedness and destitution. He was buried by his own request near Chaucer in Westminster Abbey, at the expense of the earl of Essex, who is said, in the account by Jonson, to have tendered him succor on his death-bed, though too late to be of any avail.

Spenser takes admitted rank as one of the very greatest of English poets; and his chief work, the *Faerie Queene*, written in that stateliest of English measures, since known by the name of its inventor, tedious as it is in its allegory, and in much of its diction obsolete even when written, is a masterpiece of opulent genius. In the poetry of Spenser, an ever-present seeking for and sense of beauty finds its fit expression and reflex in a fluent succession of sweet and various cadences; in breadth and splendor of pictorial effect, it has never, perhaps, been surpassed; such a lavish exuberance in detail as we find in it, has seldom been so combined with a total impression of chastened and majestic sobriety; and throughout it is pervaded by that atmosphere of moral wisdom and serenity which Milton reverently recognizes in "the sage and serious Spenser."—See *Spenser and his Poetry*, by Prof. G. L. Craik (3 vols., 1845). The most complete editions of the poet's works are those by Todd (1806) and Collier (1862); but a new edition by Grosart, and others appeared in 1882. Church's short life of S. is admirable.

SPENSERIAN STANZA. See METER.

SPERANSKI, MIKHAIL, Count, 1772-1839; b. Russia; prof. of mathematics at St. Petersburg in 1797, and sec. to the council of the empire in 1801. He became asst. minister of justice in 1808. During his administration he remodeled the system of taxation, introduced a new penal code and a system of national education. He was banished in 1812, but recalled in 1816. He became president of chancery under Nicholas.

SPERMACETI is a waxy substance obtained from cavities in the head of the sperm whale, *physeter macrocephalus*. In the living whale it is dissolved in an oil, but on cooling separates as a solid. As much as twelve barrels of crude spermaceti are obtained from an ordinary whale. It is purified by pressure, melting, and crystallization. It is white or translucent, crystallizable from alcohol and ether, not soluble in water, smooth to the touch, and without taste or odor. It becomes rancid and grows yellowish on exposure to light. It burns with a bright flame. Its specific gravity is .943, and its melting point between 45° and 50° C. (113° to 122° F.). It does not, like fats and oils, give glycerine after saponification, but cetyl alcohol. It consists chiefly of cetin, or cetyl palmitate, $\left. \begin{matrix} C_{16}H_{31}O \\ C_{16}H_{33} \end{matrix} \right\} O$; but from its decompositions seems to contain also lauric, myristic, and stearic acids in small quantities, combined with alcohols of the same name.

Spermaceti has been used in medicine as a demulcent or soothing application to mucous membranes, but has manifested no particular virtue. It is, however, used as an ingredient of many ointments and cerates. It is made into sperm candles of definite weight for photometric purposes.

SPERMATOZO A is the term given to the true fertilizing agents occurring in the male generative organs. They appear to be formed from the epithelial lining of the tortuous seminal tubes, of which the organ known as the *testis* is essentially composed. At the period of puberty in man, and at certain periods annually in other animals, the seminal tubes are seen to be filled with cells, from which the spermatozoa are developed. Without describing the various changes that ensue, we may observe, that the spermatozoa are finally set free by the bursting of the cell-walls, and arrange themselves in parcels symmetrically placed, with the so-called heads in one direction, and the tails in the opposite direction. In the human subject, the spermatozoa may be described as clear, hyaloid bodies, each of which consists of a dilated portion, the head or body, from which a long tail, or filament, issues. The head is flattened from side to side, and of a conical form, the pointed extremity being anterior. The length of the spermatozoa is about $\frac{1}{800}$ of an inch. The spermatozoa of different animals vary extremely in size and form; and for a detailed account of these bodies, in different classes of animals, we must refer to the article "semen," in the *Cyclopædia of Anatomy and Physiology*. It was formerly supposed that spermatozoa were independent organisms (like the infusoria for example), but it is now known that they must be regarded as epithelial cells (or perhaps nuclei), modified in structure, and endowed with special properties. That the integrity of the spermatozoa is essential for the process of impregnation, is a fact that cannot be called in question; but of the nature of the force which they communicate to the ova, we know nothing.

SPEY, a river in Scotland, between Badenoch and Lochaber, expands into the small Loch Spey, 6 m. n.w. of loch Laggan, follows a north-eastern direction through the counties of Inverness and Elgin, and, after a course of about 110 m., falls into the Morey firth, 3 m. w. of Port-Gordon. During a portion of its lower course, it forms the boundary between the counties of Elgin and Banff. In point of length, the Spey is the second river of Scotland, but except for its salmon-fisheries, it is almost without value, nor can it be called a picturesque stream. It has the swiftest current of all the large rivers in Britain, and is subject to sudden and violent freshets, resulting at times in disastrous inundations. Its salmon-fisheries are very valuable.

SPEYER, also **SPIER** (Fr. *Spires*), the capital of Rhenish Bavaria (the former Palatinate), and one of the oldest towns in Germany, stands at the influx of the Speyerbach into the Rhine, 16 m. s.w. of Heidelberg, and 23 n. of Carlsruhe. It is connected with Mannheim, and thence with the rest of Germany, by railway. The principal building is the cathedral (founded 1030), which contains the tombs of numerous emperors of Germany. Since 1854 it has been wholly renewed, and is the grandest specimen of Romanesque architecture in Europe. The interior is adorned with 32 magnificent frescos by Schraudolph.

Except the cathedral and a ruined wall, the sole relic of the imperial palace in which twenty-nine diets were held—at one of which (1529) the reformers made their famous "protest," and got for themselves the name of Protestants (see **PROTESTANT**)—Speyer does not contain a single ancient building. This is owing to the fact that in the Orleans succession war—well called by the Germans the *Mordbrenner Krieg*—during which the whole Palatinate was savagely wasted, Speyer was taken by the French, its inhabitants driven out, and the city blown up with gunpowder, and burned to the ground. Only the cathedral resisted the barbarous efforts to mine it. Everything else was reduced to rubbish, and for long years the noble old pile overlooked nothing but a melancholy waste of ruins. In 1794 it was wasted by the French under Custine, and has never recovered from these calamities. Speyer manufactures vinegar and tobacco, and has some transit-trade on the Rhine. Pop. '85, 16,064, of whom about two-fifths are Catholics.

Speyer is the *Noviomagus* of the Romans, and was the capital city of the Nemetes, a German people. Speyer was probably the native name from the first, for in some of the later Roman notices it is called *Civitas Nemetum, id est Spira*. The name is derived from the stream, or *bach* (Speyerbach), which here flows into the Rhine. A Christian community appears to have been established here as early as 150–200 A.D., and it was certainly the seat of a bishop about 300 A.D. The German emperors had here a *pfalz* (palace, Lat. *palatium*, whence the former name of the region of which it was the capital, the Pfalz or Palatinate), in which they often resided. By them the town was made a free city of the empire; and having obtained the monopoly of the carrying-trade up and down the Rhine, it rapidly rose in wealth and importance. The *Reichskammergericht*, or imperial chamber of justice, the highest court of the German empire, was held here for 200 years, until removed to Wetzlar in 1689. Speyer has been twice in possession of the French, but has belonged to Bavaria since 1815.

SPEZIA, a city of northern Italy, province of Genoa, and 56 m. s.e. of the city of that name. Pop. '81, 19,864. It is situated near the inner point of the gulf of Spezia. The

gulf is formed by the bifurcation of a spur of the Apennines, and is $3\frac{1}{2}$ m. long, and 3 m. broad; its western shore is indented by many coves or creeks, five of which—Porto-Venere, La Castagna, the Varignano (the Quarantine station), Grazie, and Panigaglia—are so deep that large men-of-war may be moored in them. The emperor Napoleon I. recognized the importance of this gulf, and at one time designed, it is said, to make it the chief naval station of his empire in the Mediterranean. The Italian government has made it the station for its ships of war, and it is now the chief arsenal of the kingdom. Its shipping and commerce are considerable, and the construction of a commercial harbor, to the east of the town, was begun in 1890. The scenery of the gulf is very beautiful, and the mildness of its climate was famous in ancient times, when it was known as the gulf of Luna. The soil produces olives, excellent wines, fruits, etc., and the town has become within recent years a much-frequented health resort in winter. There are numerous foreign consulates. The railway from Genoa to Spezia was completed in 1873.

SPEZZIA (the ancient *Tiparenos*), a small Greek island at the entrance to the Gulf of Nauplia. The island is unfruitful, and its people are engaged chiefly in commercial pursuits. The population in 1889 was 5192, of whom 5172 lived in the town of Spezia, on the n. coast of the island.

SPHERULARIA, a very remarkable nematode, or round worm, which exists as a parasite in various species of bees. The female is almost an inch in length, has a nearly uniform diameter of $\frac{1}{8}$ of an in. is, of a whitish color, is bluntly pointed at each end, and is covered with numerous (about 800) small button-like projections—a peculiarity to which it owes its name. There is neither mouth, esophagus, intestine, nor anus, and the whole animal consists of little more than an elongated mass of fatty tissue and reproductive organs, which in full-grown individuals contain ova in various stages of development. Although the female was discovered in 1836 (by Leon Dufour), it was not until Jan. 1861 that the discovery of the male was announced by Mr. Lubbock in his memoir on this parasite in *The Natural History Review*. The male is more than 28,000 times smaller than the female, which accounts for its having been previously overlooked. It is frequently found sexually united to the female in the same manner as occurs in *sclerostoma syngamus* (q. v.), the parasite which gives rise to the *gapes* in various birds.

SPHAGNUM, a genus of moss, whose spore-case is an urn closed by a deciduous lid, and its brim toothless, the calyptra irregularly torn. Several species are natives of Britain, and are common in bogs, from which they derive their popular name, Bog Moss. They are remarkable for the whitish color of their leaves. They are very elegant plants. They often grow in considerable masses, absorbing water like a sponge, but becoming friable when dry. They contribute much to the formation of peat. Gardeners employ them in preference to other mosses for covering the roots of plants and keeping them moist, as they have in a high degree the property of absorbing moisture from the atmosphere. They have been used as food in barbarous countries, but are very slightly nutritive. The cells of the leaves are remarkable for their spiral structure, and for large pores in their sides. See illus., *MOSSSES*, vol. X.

SPHEGIDÆ, or **SPHECIDÆ**, a family of hymenopterous insects, winged in both sexes, and much resembling bees or wasps in general appearance. They are solitary in their habits. Many of them burrow in sand, and are known as *sand-wasps*. They are extremely active and restless, and may be seen running about on sand-hills, with their wings in constant motion. Some of them carry spiders, and others caterpillars, into their burrows, as food for their larvæ, placing them there when the egg is laid, and stinging them so as to render them torpid, without killing them. They display wonderful energy and perseverance in dragging the spider or caterpillar to the burrow. They are mostly tropical insects. See illus., *BUTTERFLIES, ETC.*, vol. III.

SPHENISCIDÆ, the penguin family, or a sub-family of *brevipennatæ*, belonging to the order *natatores*, or swimmers. The principal or typical genus is *spheniscus*. The penguins occupy in the southern hemisphere the place filled by the auks in the northern. See *AUK*. They live gregariously in the seas of the southern hemisphere on the coasts of south Africa and South America, especially at Terra del Fuego, and on the solitary islands of the South Pacific. The *spheniscidæ* contain the genera *spheniscus*, *eudyptes*, *pygoscelis*, and *apterodytes*. The *apterodytes patagonica*, or the king penguin, is the most remarkable. Mr. G. Bennett, who saw them at Macquarrie island in the southern Pacific (see *PENGUIN*), says: "They are arranged when on shore in as compact a manner and in regular ranks as a regiment of soldiers; and are classed with the greatest order, the young birds being in one situation, the molting birds in another, the sitting hens in a third, the clean birds in a fourth, etc.; and so strictly do birds in similar condition congregate that, should a bird that is molting intrude itself among those which are clean, it is immediately ejected from them. The females hatch the eggs by keeping them close between their thighs; and if approached during the time of incubation, move away, carrying their eggs with them. At this time the male bird goes to sea and collects food for the female, which becomes very fat. After the young is hatched both parents go to sea and bring home food for it. It soon becomes so fat as scarcely to be able to walk, the old birds getting very thin." Capt. Fitzroy gives the

following account of the manner of feeding the young of the jackass penguin, *spheniscus demersus*, at Noir island: "The old bird gets on a little eminence and makes a great noise (between quacking and braying), holding its head up in the air as if it were haranguing the penguinery, while the young one stands close to it, but a little lower. The old bird, having continued its clatter for about a minute, puts its head down and opens its mouth widely, into which the young one thrusts its head, and then appears to suck from the throat of its mother for a minute or two, after which the clatter is repeated, and the young one is again fed; this continues for about ten minutes." Mr. Darwin relates an encounter with one of these birds on the Falkland islands: "I was much amused by watching its habits. It was a brave bird; and until reaching the sea it regularly fought and drove me backward. Nothing less than heavy blows would have stopped him; every inch gained he firmly kept standing close before me, erect and determined. When thus opposed he continually rolled his head from side to side, in a very odd manner, as if the power of vision only lay in the anterior and basal part of each eye."

SPHENOID BONE (Gr. *sphên*, a wedge, and *eidos*, form) is situated at the anterior part of

the base of the skull, and articulated with all the other cranial bones, which it wedges firmly together. It somewhat resembles a bat with its wings extended, and hence was termed the *os vesperilionis*. It is divisible into a body, the greater and lesser wings, and various processes. The greater wings present three surfaces: a superior or cerebral surface, forming part of the floor on which the brain rests; an anterior surface, which assists to form the outer part of the orbit of the eye, and an external surface with a rough ridge, giving attachment to the external pterygoid muscle, one of the most powerful muscles of mastication. The second, third, fourth, fifth, and sixth cranial nerves emerge from the cranial cavity through foramina in this bone. Although considered in human anatomy as a single bone, it may be regarded as composed of several bones, which, after a time, unite with one another, as the basi-sphenoid, the pre-sphenoid, the ali-sphenoid, and the orbito-sphenoid bones.

The upper or cerebral of the sphenoid bone:

1. The olivary process; 2, the ethmoidal spore; 3 and 4, the lesser and greater wings on the left side; 6, the extremity of left pterygoid process; 7, the foramen for the optic nerve; 10, the sella turcica on which the pituitary gland rests; 12, the basilar portion of the bone, joining with the occipital; 13, part of the sphenoidal fissure which separates the greater from the lesser wings, and transmits the 3d, 4th, the ophthalmic division of the 5th, and the 6th nerves, with the ophthalmic vein; 14, the foramen rotundum, transmitting the second division of the 5th nerve; 15, the foramen ovula, transmitting the third division of the 5th nerve; 16, the foramen sponosum for the passage of the middle meningeal artery.

SPHERE, a regular solid figure, every point of whose surface is equally distant from its center; and whose outline is traced by a circle revolving round its diameter. All sections of a sphere by a plane are necessarily circles, and all sections by planes passing through the center, or by planes cutting the sphere at equal distances from the center, are equal. The former sections are called *great*, and the latter *small, circles*. Small circles may vary in size between a mere point and a great circle, approaching either limit as nearly as we please. The surface of a sphere is equal to that of four of its great circles, or (taking x for the radius of the sphere) to $4\pi x^2$; and its volume to that of a cone whose altitude is twice that of the sphere, or $4x$, and whose base is a great circle of the sphere, the formula for it being $\frac{4x}{3} \times \pi x^2$, or $\frac{4}{3}\pi x^3$. The most remarkable geometrical

property of the sphere is the relation which its surface and volume bear to those of the "circumscribing" cylinder, i.e., a cylinder whose length and diameter of each end are each equal to the diameter of the sphere, and in which, therefore, the sphere will be exactly contained. The concave surface of such a cylinder is exactly equal to the surface of the sphere; and not only so, but if a section parallel to the base of the cylinder be made through both cylinder and sphere, the curved surfaces of the portions cut off are equal, whether such portion be cut off from one end or be intercepted between two parallel sections; it follows from this that the curved surface of any section of a sphere with parallel ends is equal to the product of the circumference of a great circle of the sphere by the height or thickness of the section, and that the curved surfaces of all sections of a sphere are proportional to the thickness of such sections. The volume of the sphere, also, is equal to two-thirds of that of the circumscribing cylinder.

SPHEROGRAPH, a simple and exceedingly efficient instrument for the mechanical solution of such problems in spherical trigonometry as navigation, geography, etc., present, was invented in 1856 by Mr. Stephen Martin Saxby, R.N. It consists of two circular pieces of paper, the whole of the under and the rim of the upper being made of stout card-board, and the interior portion of the upper one of strong transparent tracing-paper; these two circles are attached by a pin through their common center, the pin being made to work in an ivory collar, so as to prevent any lateral motion of either circle. Round the pin as center, equal circles are drawn, one on each sheet; each circle

is then filled in with lines representing meridians and parallels according to the stereographic projection, and the instrument is completed. As one of the chief uses of the spherograph is to show the course, distance, and differences of latitude and longitude in "great circle sailing" (q.v.), we shall give a problem of this sort in illustration of the

FIG. 1.

X represents the point to be arrived at, and consequently PX, the arc of a great circle passing through P and X, is the great circle track, PD is the difference of latitude, EF the difference of longitude; the spherical angle XPD, measured by GH, an arc of a great circle, of which P is the pole, is the course; and the length of PX is measured by PT, the portion of PS which is cut off by a parallel of the under circle through X, in degrees. The data, then, being as above, we find by inspection of the instrument the difference of lat. = 40° s., the difference of long. = 60° w., the course = $s. 72\frac{1}{2}^{\circ}$ w., and the distance = $63\frac{1}{2} = 3,800$ nautical miles. Besides the saving of time and labor by the use of this instrument—the whole work being the *setting* of the instrument, and then the reading off of the required elements—it is evident that the substitution of a mechanical solution for calculation greatly lessens the probability of error. It is found that spherographs of 5 in. radius give results of sufficient accuracy for all the purposes of the navigator.

All other spherical problems can be solved with equal facility by this instrument, but one more example will suffice. Let Z (fig. 2) now represent the zenith of a place, ZHNR its meridian, P the north pole of the heavens; the other lines are then circles of declination, altitude, azimuth, and hour circles; and let O represent the place of the sun in given declination and altitude at a certain time. The instrument is now set by turning round the upper card till the point O (determined by its circle of declination and hour circle) on the under card falls upon the circle of given altitude on the upper card, then d is the sun's place at noon, Hd being his meridian altitude, PR the latitude of the place, the angle RPS (measured in degrees along QE) the time of sunset, ds half the length of the day, so half the length of the night, etc. The spherograph is also useful in finding latitude when the horizon is hid by fogs, right ascensions at night, and in correcting lunar observations; but for these purposes, spherographs are specially constructed, as some slight variations in the form given above are necessary.

FIG. 2.

SPHEROID is a species of ellipsoid (q.v.), and is represented by the same equation. If an ellipse be made to revolve round one of its axes, the curved outline of the ellipse describes the spheroid. Should the major or longer axis be the axis of revolution, the spheroid is said to be *prolate* (Lat. *prolatus*, lengthened), but if the minor or shorter axis, *oblate*. The earth's axis of revolution, which runs from pole to pole, being about 25 m. shorter than the longest or equatorial diameter, and these being at right angles to each other, the earth is considered as an oblate spheroid.

SPHEROIDAL CONDITION of liquids is the name usually given to a series of very singular phenomena discovered by Leidenfrost, but first carefully investigated by Bontigny. Indeed, one, at least, of these phenomena has been popularly known for a very long time, being the foundation of the rough practical method of determining whether or not a flat-iron is so hot as to be likely to singe the linen to which it is to be applied. The test consists simply in letting a drop of water fall upon the iron; if it be not too hot, the drop spreads over the surface and evaporates. If it be too hot, the drop at once glances off the iron without wetting it.

The common experimental method of exhibiting the spheroidal condition is easily performed thus: A metallic disk, slightly concave, like a watch-case, is heated by a lamp, and water is cautiously dropped on it from a pipette. If this be done before the disk is sufficiently heated, the water boils almost explosively, and is dispersed at once in vapor. But when the disk is hot enough, the water remains suspended *above* the surface; and the drop, when small, takes nearly the form of an oblate spheroid. Various proofs have been given, though they are obviously unnecessary, that there is no contact in this case. Thus, if the disk be very nearly flat, light passes freely between it and the drop. Again, if one pole of a galvanic battery be connected with the disk, and the other be dipped into the drop, a galvanometer interposed in the circuit shows that no current passes. By heating the disk sufficiently, and dropping on the water very carefully, we may easily keep in the spheroidal state as much water as, if not more than, it could hold when cold. The explanation of the phenomenon is not yet quite clear; but there is no doubt that the radiant heat from the disk raises vapor so freely from the surface of the drop nearest it, as to interpose a cushion of dense and highly heated vapor between them, on which the drop, as it were, floats; the pressure of the vapor balancing its weight. This is not, however, a quite complete explanation of the experiment, and it would require too much detail to examine it more closely. But the most curious fact connected with the experiment is, that the water does *not* boil. In fact, it evaporates so freely that the heat carried off from it, as latent heat, by the vapor which is constantly formed, keeps its temperature somewhere about 206° F. only. This suggests a curious experiment, which is found to succeed. *Boiling* water, dropped on a red-hot plate of metal, instantly assumes the spheroidal state, and is *cooled* six degrees below boiling.

It is not necessary that a metal plate be used—a watch-glass will suffice for the experiment; but *hot* water must be dropped on it, else the glass will crack.

Other liquids, and even some bodies which are solid at ordinary temperatures, can be easily brought into the spheroidal state—the lowest requisite temperature of the disk being dependent on the boiling point of the substance. Thus, while water has a temperature of 206° F. in the spheroidal state, the disk must have a temperature of 340° F. at least. For alcohol, these temperatures are 168° F. and 270° F.; for ether, 94° F. and 140° F. A good example of a solid entering this state is furnished by dropping crystals of iodine on a hot platinum disk.

It is not necessary that the disk should be solid; it is easy to obtain ether, and even water, in the spheroidal state over the surface of hot oil—but great care is required, as explosions are apt to occur, in which case the hot oil is freely thrown about.

Many cases of bursting of steam-boilers, otherwise apparently inexplicable, seem to be attributable to this condition of matter. Thus, if we suppose that the water-supply has run low, and the boiler has been overheated, it is conceivable that the contents may sometimes be in the spheroidal state. The addition of cold water in such a case would bring them suddenly *in contact* with the overheated metal, and large quantities of steam would be generated with violence.

A very singular experiment, the freezing of water on a red-hot plate, is easily performed by the help of this property of matter. Liquid sulphurous acid is so volatile as to have a temperature of 13° Fahr. only, when in the spheroidal condition. As this is 19° under the freezing-point of water, if a little water be dropped into the spheroid of acid, it is at once frozen, and the pellet of ice can be dropped on the hand from the still red-hot plate.

Even mercury can be frozen by a similar process, but as much greater cold is required, the substance in the spheroidal state is a mixture of solid carbonic acid and ether.

The hand may be dipped for a short time with impunity into melted lead, and even into melted copper. The vapor, instantly raised from the moisture of the skin, prevents, so long as that moisture lasts, more than an endurable amount of radiant heat from reaching the hand, and also prevents direct contact. It is probable that a knowledge of some forms of this phenomenon, in old days, was employed by priestcraft for the purpose of protecting, when it was desirable to do so, the victims of the ordeal (q.v.) by fire.

The phenomenon may easily be reversed. Thus, a red-hot silver ball, dropped into a vessel of water, is seen to glow for some time, till it has so far cooled that the water comes into contact with it, when we have, as in the other form of the experiment, an immediate and violent formation of vapor. The success of this experiment is greatly aided by the addition of some strong ammonia to the water.

SPHINCTER MUSCLES (Gr. *sphinktēr*, that which binds tight) are circular bands of muscular fibers, whose function is to antagonize the expellent action of certain viscera, especially the bladder and the lower part of the intestinal canal. It is to the presence of these muscles that the higher animals owe the power of retaining for a considerable period the excrementitious matters collected in the bladder and rectum, and of discharging them at intervals, the sphincter muscles, being like those engaged in the process of respiration, mainly, but not entirely, under the control of the will. Under certain conditions, however, the necessity for expelling the contents of these viscera becomes so urgent that the sphincters lose their ordinary voluntary power.

SPHINX, a Greek word, signifying the squeezer or strangler, applied to certain symbolical forms of Egyptian origin, having the body of a lion, a human or an animal head, and two wings attached to the sides. Various other combinations of animal forms have been called by this name, although they are rather griffins or chimeras. Human-headed sphinxes have been called androsphinxes; one with the head of a ram, a criosphinx; with a hawk's head, a hieracosphinx. The form, when complete, had wings added at the sides; but these are of a later period, and seem to have originated with the Babylonians or Assyrians. In the Egyptian hieroglyphs, the sphinx bears the name of *Neb*, or lord, and *Akar*, or intelligence, corresponding to the account of Clemens, that these emblematic figures depicted intellect and force. The idea that they allegorized the overflow of the Nile when the sun was in the constellations Leo and Virgo appears quite unfounded. In Egypt the sphinx also appears as the symbolical form of the monarch considered as a conqueror, the head of the reigning king being placed upon a lion's body, the face bearded, and the usual dress-drapery being suspended before it. Thus used, the sphinx was generally male; but in the case of female rulers, the figure has a female head and the body of a lioness.

The most remarkable sphinx is the Great Sphinx at Gizeh, a colossal form, hewn out of the natural rock, and lying 300 ft. e. of the second pyramid. It is sculptured out of a spur of the rock itself, to which masonry has been added in certain places, to complete the form, and measures 172 ft. 6 in. long by 56 ft. high. Immediately in front of the breast, Caviglia found, in 1816, a small naos, or chapel, formed of three hieroglyphical tablets, dedicated by the monarchs Thothmes III. and Ramesses II. to the sphinx, whom they adore under the name of Heremakhu, or Harmachis, as the Greek inscriptions found at the same place call it—i.e., the sun on the horizon. These tablets formed three walls of the chapel; the fourth, in front, had a door in the center, and two couchant lions placed upon it. A small lion was found on the pavement, and an altar between its fore-paws, apparently for sacrifices offered to it in the time of the Romans. Before the altar was a paved esplanade or dromos, leading to a staircase of thirty steps placed between two walls, and repaired in the reigns of M. Aurelius and L. Verus, May 10, 166 A.D. In the reign of Severus and his sons, 199–200 A.D., another dromos in the same line as the first, and a diverging staircase, were made, while some additions were found to have been made to the parts between the two staircases in the reign of Nero. Votive inscriptions of the Roman period, some as late as the 3d c., were discovered in the walls and constructions. On the second digit of the left claw of the sphinx, an inscription, in pentameter Greek verses, by Arrian, probably of the time of Severus, was discovered. Another metrical and prosaic inscription was also found. In addition to these walls of unburnt brick, galleries and shafts were found in the rear of the sphinx, extending northward. The excavations, however, of M. Mariette, in 1852, have thrown further light on the sphinx, discovering the peribolos, or outer wall that encircled it; that the head only was sculptured, and that the sand which had accumulated round it was brought by the hands of man, and not an encroachment of the desert; also that the masonry of the belly was supported by a kind of abutment. To the s. of the sphinx, Mariette found a dromos, which led to a temple built at the time of the 4th dynasty, of huge blocks of alabaster and red granite. In the midst of the great chamber of this temple were found seven statues, five mutilated and two entire, of the monarch Shaf-ra or Cephren, made of a porphyritic granite. They are fine examples of ancient Egyptian art. While the beauty and grandeur of the Great Sphinx have often attracted the admiration of travelers, its age has always remained a subject of doubt, but these later discoveries prove it to have been a monument of the age of the 4th dynasty, or contemporary with the pyramids. See *illus., Egypt, vol. V., p. 294, fig. 2.*

Besides the great Sphinx, avenues of Sphinxes have been discovered at Saqqarah, forming a dromos to the Serapeum of Memphis, and another dromos of the same at the Wady Esseboua. A Sphinx of the age of the shepherd dynasty has been found at Tannus, and another of the same age is in the Louvre; and a granite Sphinx, found behind the vocal Memnon, and inscribed with the name of Amenophis III., is at St. Petersburg. An avenue of criosphinxes has been found at Karnak. These are each about 17 ft. long,

and of the age of Horus, one of the last monarchs of the 18th dynasty. Various small Sphinxes are in the different collections of Europe, but none of any very great antiquity.

The Theban Sphinx, whose myth first appears in Hesiod, is described as having a lion's body, female head, bird's wings, and serpent's tail, ideas probably derived from Phenician sources, which had adopted this symbolical form into the mythology from Egypt. She was said to be the issue of Orthos, the two-headed dog of Geryon, by Chimæra, or of Typhon and Echidna, and was sent into the vicinity of Thebes by Juno, to punish the transgression of Laius, or, according to other accounts, by Bacchus, Mars, or Pluto. See *ŒDIPUS*. The Sphinx was a favorite subject of ancient art, and appears in bas-reliefs, on medals of Chios and other towns, and often as the decorations of arms and furniture. In Assyria and Babylonia, representations of Sphinxes have been found, and the same are not uncommon on Phenician works of art.

SPHINX. See *HAWK-MOTH*.

SPHYGMOGRAPH, an instrument by which we ascertain, and permanently record, the form, force, and frequency of the pulse-beat, and the changes which that beat undergoes in certain morbid states. This instrument consists of two essential parts: (1) Of two levers, one of which is so delicately adjusted on the vessel the pulsation of which it is desired to examine, that on each expansion of the vessel the lever undergoes a corresponding slight elevation: this lever communicates by a perpendicular arm with a second, to which it transmits the impulse received from the vessel; the extremity of this second lever is armed with a pen-point, which records the movements thus indicated on a movable plate, controlled by the second part of the instrument. (2) The second portion consists of a plate, moved by watch-work, and bearing a strip of paper on which the *sphygmographic* tracery is formed.

Mode in which the Tracery is formed.—As the pulse transmits through the levers a vertical movement to the pen-point, and the plate, on which the tracery is formed, is moved steadily across the pen-point, an undulating line is the result: the *height* of the elevations indicating the strength of the pulse; and the *number* of the elevations delineated in the time the pen takes to travel its frequency. The tracings produced by the pulse at the wrist in forms of cardiac disease exhibit the manner in which the tracing is modified in diseased states of the circulatory system. In the case of a patient suffering from an incompetent state of the valves guarding the orifice of the aorta, the great vessel conveying blood from the heart, the blood, when propelled into the aorta, distends it, and communicates a pulse throughout the arterial system. When the vessel again contracts, regurgitation takes place into the cavity of the heart, as the valves, which should prevent this regurgitation, and maintain the arterial tension, are unable to perform their function. The pulse-beat is accordingly abrupt, and of short duration, and the sphygmographic tracing presents a series of abrupt elevations and depressions. In a different form of cardiac disease, in which the valves are so affected as to obstruct the passage of the blood into the circulation, the effect on the pulse is to render its beats weakly marked and irregular; and in the sphygmographic tracing, the elevations are diminished in height and regularity. The pulse, in extreme forms of this lesion, is represented in sphygmographic tracing by a slightly waving line.

SPHYRÆNIDÆ, a family of fishes included by Cuvier in *Percidæ*, but having the ventral fins far behind the pectorals, and the bones of the pelvis quite detached from those of the shoulder. The form is elongated; there are two dorsal fins; the scales are small and cycloid; the mouth very large, with strong sharp teeth. The species are found in the Mediterranean and in tropical seas. Some attain a large size, as the *BARRACOUA*, or *Barracouda Pike* (*Sphyræna barracouda*), an inhabitant of the tropical parts of the Atlantic ocean, which is scarcely less formidable than the white shark. It is, however, held in considerable estimation as an article of food, but at some seasons of the year becomes unwholesome. It is a beautiful fish, of a rich green color above, and white beneath. The *BECCUNA* (*S. vulgaris*) is also valued as an article of food, and its scales and air-bladder yield a substance used for making artificial pearls.

SPICCA' TO (Ital. separated), a musical term, indicative, like *Staccato* (q. v.), of a distinct and detached mode of performance. Its usual application is to music for bowed instruments, where it implies that each note is to have a bow distinct from that which precedes or follows it.

SPICE ISLANDS. See *MOLUCCAS*.

SPICES (Lat. *species*, kinds; in later Latin, kinds of goods, or produce in general; and then, the most highly prized kind of goods, the aromatic productions of the east), aromatic and pungent vegetable substances, used as condiments and for flavoring food. They are almost exclusively the productions of tropical countries. In ancient times, and throughout the middle ages, all the spices known in Europe were brought from the east; and Arabia was regarded as the land of spices, but rather because they came

through it, or were brought by its merchants, than because they were produced in it, for they were really derived from the further east. They owe their aroma and pungency chiefly to essential oils which they contain. They are yielded by different parts of plants; some, as pepper, cayenne pepper, pimento, nutmeg, mace, and vanilla being the fruit or particular parts of the fruit; while some, as ginger, are the root-stock; and others, as cinnamon and cassia, are the bark. Tropical America produces some of the spices, being the native region of cayenne pepper, pimento, and vanilla; but the greater number are from the East Indies.

SPIDER, *Aranea*, a Linnaean genus, now divided not only into many genera, but into many families, and constituting a section (*araneida*) of the class *arachnida*, and order *pulmonaria*. The species are very numerous, and are found in all parts of the world, but most abundantly in tropical countries, which also produce the largest species, some of them capable of making very small birds, and not merely insects, their prey (see BIRD-CATCHING SPIDER). The *cephalothorax*, formed by the combination of the head and thorax into one piece, is covered with a kind of horny buckler, generally of an oval form; the abdomen is attached to it by a short stalk, and is generally soft and tumid. Each of the eight legs consists of seven joints, the last armed with two hooks, which are commonly toothed like a comb. The *frontal claws*, commonly called *mandibles*—which do not, however, correspond to the mandibles of insects, and move in an entirely different direction, up and down—are terminated by a sharp movable hook, which has near its extremity a small slit for the emission of a venomous fluid secreted in a gland of the previous joint. The *maxillæ* are two in number, and between them is an organ called the *tongue*, forming part of the external apparatus of the mouth. The *maxillæ* are the basal joints of the *pulpi*, which resemble very small legs, and are often terminated in the females by a small hook, but in the males by complicated and curious appendages, characteristic of the different genera and species. Spiders have generally eight eyes, the relative position of which varies remarkably in the different families and genera. A few species have only six eyes, and a very small number have only two. The upper surface of the abdomen generally exhibits a number of impressed spots, most conspicuous in those kinds which have a smooth naked skin. The pulmonary orifices are either two or four in number, and are situated near the base of the abdomen. Near the anus are several *spinnerets*, small protuberances, pierced at the extremity with a multitude of minute orifices, from which threads of extreme tenuity are produced, all these threads combining to form one thread of the *web*. The substance which exudes from the spinnerets is glutinous, and immediately dries into thread on coming in contact with the air. It is elaborated in reservoirs, which terminate in intestine-like tubes. All spiders have spinnerets, and produce threads, although all do not use them for the same purposes; for they differ very much in their habits: some employ their webs in order to catch their insect prey, while others depend for the capture of their prey on their powers of running and leaping; and some weave for themselves habitations in which they live, while others select holes and crevices as their places of abode. Almost all spiders envelop their eggs in silken cocoons, which some of them tear open when the young are hatched; they are attentive to their young, some carrying them for a time on their back, while some carry the cocoons or egg-cases beneath their breast, and others carry them attached to the extremity of the abdomen. Nearly 2,000 eggs have been found in a single cocoon, and the young, when set free, may be seen swarming over the body of the mother, so as almost to conceal her from view. The female spider is, in many of the species, much larger than the male, and a very remarkable danger attends the amatory approaches of the latter, as, if they are not favorably received, he is not uncommonly killed and eaten on the spot. Spiders are very pugnacious, and in their combats often sustain the loss of limbs; but, like crustaceans, they possess the power of repairing this loss. Like them also, they change their skin frequently during their growth; but they undergo no proper transformation. There is much similarity of form among all the multitude of kinds. Many of them exhibit very brilliant and beautiful colors, among which are some of the American species, to be found in fields and moors, although the common house spider (*aranea domestica*) is of very unattractive appearance.

All spiders kill the insects and other small creatures on which they prey by means of their venomous mandibles, and the bite of a house spider is quickly fatal to a house-fly. The bite of the larger species is dreaded even by man, being very painful, and not only producing much inflammation and swelling, but often much fever. Death has been known to ensue.

Spiders' webs have long been in high repute for stanching wounds. Threads of this material are also employed for the cross-wires of astronomical telescopes. Textile fabrics have been made of it, but only as articles of curiosity.

Spiders have been arranged by Walcknaer in five principal groups, distinguished by their habits. (1.) *Hunting spiders*, which incessantly run about in the vicinity of their abode in quest of prey, some of them weaving silken tubes, in which they dwell, others hiding in fissures; some remarkable for the swiftness with which they run, others for their power of leaping in order to seize their prey. Some of them are of large size. Livingstone mentions a South African one which can leap a distance of one foot. A small one is common on windows in Britain in summer, and, when leaping, avoids the

danger of falling from the window by suspending itself at the same moment by a thread. (2.) *Wandering spiders*, which have no fixed residence, have the power of running sideways or backwards, and throw out threads to entrap prey, but do not weave them into regular webs. Some of them live among plants, and place their egg-cases on leaves, the edges of which they bind together with their silk. (3.) *Prowling spiders*, which have nests, but prowl about in their neighborhood, or in that of the threads which they spread to catch prey. (4.) *Sedentary spiders*, such as the common house spider, which spin large webs, and lie in wait at the middle or at the side. These are subdivided according to the fashion and structure of their webs. (5.) *Water spiders*, which resemble the last group in their habits, except that they live in water, generally among the stems and leaves of aquatic plants, where they construct their webs. A very interesting species, one of the most interesting possible inmates of an aquarium, is the common water spider (*argyroneta aquatica*) of Britain, not unfrequently to be found in deep ditches and ponds in some parts of England. It is of a brownish color, densely covered with hairs, which are of great importance in its economy, entangling air, which the animal carries down with it into the water, to supply its pulmonary sacs; for the water spiders all breathe by the same kind of organs as their terrestrial congeners. The eggs of the water spider are attached to the leaves or stems of plants under the surface of the water, and are protected by a dome-shaped web, so close in its structure as to retain the air which is brought into it, and in which the spider itself lives, bringing down air on its furred body till the dome is filled. The entrance is from below.—The most curious nests are those of the trap-door spiders, belonging to the group *territelariæ*, or underground weavers. The nest is a tubular burrow, lined with silk, and having the entrance covered with a circular lid of the same material attached to the edge of the lining by a kind of hinge. In the most common form of nest, the lid is made thick by having layers of earth between the layers of silk, and fits like a cork into the mouth of the tube, which is beveled to receive it. As mosses grow on the lid as well as on the surrounding ground, the concealment is complete. In some types of nest, there is a thin external door, and then one of a more solid kind some inches below, behind which the inmate can place itself, and resist the intrusion of an enemy. In one kind of these double-door nests, a side gallery branches off from the main one, and the external door is so placed at the angle that it can be made to shut either.

SPIDER-FLY, *Ornithomyia*, a genus of dipterous insects, closely allied to the forest fly (q.v.), but the claws of the tarsi having three instead of two teeth; and the species are parasitical on birds, never on quadrupeds. *O. avicularia* frequently infests the common fowl, the blackcock, and other birds in Britain. It is greenish yellow, with smoke-colored wings.

SPIDER-MONKEY, a name often given to species of the genus *ateles*, small American monkeys, on account of their very long, slender, inelegant limbs. The tail is very long, and not only prehensile in the highest degree, but endowed with a wondrous sensitiveness of touch. These monkeys display great intelligence. It is their common practice to break nuts by means of stones; and a tame one which Dr. Gardner carried with him in his travels in Brazil, used to try a larger stone, if the first did not serve its purpose, and even to take it up in both paws, and dash it upon the nut, jumping quickly out of the way to avoid injury to its own toes. This animal generally rode on the back of a large mastiff, and in descending a steep hill, would curl its tail round the root of the mastiff's tail, to make its seat secure.

SPIEGELEISEN. See BESSEMER PROCESS; also KRUPP'S STEEL.

SPIELHAGEN, FRIEDRICH, b. Magdeburg, 1829; studied philology and philosophy at Berlin, Bonn, and Greifswald; then devoted himself to literature. He wrote *Clara Vere* (1857); *Auf der Düne* (1858); *Problematische Naturen* (1860); *Durch Nacht zum Licht* (1861); *Die von Hohenstein* (1863); *Unter Tannen* (1867); *Was die Schwalbe sang* (1872); *Quisisana* (1879); and *Uhlenhans* (1884). A collection of his novels was issued in 1895 in 22 vols. His autobiography appeared in 1890.

SPIGE'LIA, a genus of plants of the natural order *loganiaceæ*, having a calyx glandular inside, a long slender valvate, corolla, long filaments, and a capsule of two *cocci*, splitting around at the base.—*S. maritandica*, often called WORM GRASS and CAROLINA PINK, is a native of the southern United States, a perennial plant with a simple quadrangular stem. The root (PINK ROOT) is purgative, narcotic, and poisonous, but is a powerful vermifuge, and is very commonly employed in the United States.—*S. anthelmica*, an annual native of tropical America with very small purplish flowers, in spike-like racemes, possesses similar properties. The efficacy of both is, however, impaired by keeping; and they are apt to produce unpleasant symptoms when used as medicines. Other species are also known as poisons.

SPIKE, in botany, that kind of inflorescence in which sessile flowers, or flowers having very short stalks, are arranged around an axis, as in the greater plantain, common vervain, common lavender, and some species of sedge. In rye, wheat, barley, darnel, and many other grasses, there is a sort of compound spike, that is, the flowers or fruits are arranged together in spikelets, upon short stalks, which again surround the top of the

culm in the form of a spike. The catkin, the spadix, and the cone may be regarded as varieties of the spike.

SPIKENARD, or **NARD** (Gr. *Nardos*), a perfume highly prized by the ancients, and used both in baths and at feasts. It was brought from India, and was very costly. The "ointment of spikenard" (John xii. 3) was probably an oil or fat, impregnated with the perfume. The plant which produces it has been ascertained by the researches of sir William Jones and Dr. Royle to be the *nardostachys jatamansi*, the jatamansi of the Hindus, a small plant of the natural order *valerianaceæ*, a native of the mountains of the n. of India, and found at least as far s. as the Deccan. It grows on the Himalaya to an elevation of 18,000 ft. and its roots are a favorite perfume in Tibet and Nepal. The ladies of Nepal use oil in which the root has been steeped for perfuming their hair. The odor is not, however, generally agreeable to Europeans. The root, which is from 3 to 12 in. long, sends up many stems, with little spikes of purple flowers, which have four stamens.—The name spikenard was given by the ancients to perfumes used as substitutes for the true or Indian spikenard, some of which were derived from the roots of plants of the same natural order, kind called Gallic or Celtic spikenard from those of *valeriana Celtica* and *V. saluinea*, which are still used in the east for perfuming baths; and that called Cretan spikenard from those of *V. Italica*, *V. tuberosa*, and *V. phu*. All of these grow on the Alps and other mountains of the s. of Europe, and the peasantry of Styria and Carinthia collect them from rocks on the borders of perpetual snow. They are tied in bundles, and sold at a very low price to merchants, who sell them at a great profit in Turkey and Egypt, from which they are partly transmitted even to India. About sixty tons are annually exported from Trieste.

SPIKING is the operation of rendering a cannon useless without the expenditure of much time and labor. It is resorted to by troops compelled to abandon their own ordnance, or unable to remove pieces of the enemy's which they have captured. The process consists in driving a nail or spike into the vent or touch-hole. To remove it, it is recommended, if an iron gun, to load with double charge and double balls, and to fire by a train laid through the muzzle. This is supposed to loosen the spike. If the gun be of brass, a few drops of sulphuric or nitric acid on the touch-hole will render it practicable to extract the spike. If these methods fail, nothing remains but the tedious process of drilling out the spike or boring a new vent.

SPI NA BI FIDA is a congenital malformation, occurring perhaps more frequently than any other except hare-lip, and arising, like it, from arrest of development. It may be regarded as a congenital hernia of the membranes of the spinal cord, through a fissure in the wall of the bony canal. A tumor is thus formed, which is usually of a roundish shape, varying in size from that of an egg to that of an adult head, lying in the middle line of the back, fluctuating, and adhering to the adjacent vertebræ either directly or by a pedicle. The usual termination of the disease is death. As the size of the tumor increases, fatal convulsions ensue; or the skin investing the tumor may ulcerate, and the contents escape, in which case palsy or convulsions produce death. Occasional cases are, however, recorded in which patients with this affection have survived till middle life. Active surgical treatment usually hastens death, and should only be resorted to in the most urgent circumstances. Moderate support by means of a hollow truss, or a well-padded concave shield, may tend to keep the disease stationary; and any interference beyond this, is in the great majority of cases, unadvisable.

SPINACH, or **SPINAGE** (*Spinacia*), a genus of herbaceous plants, of the natural order *chenopodiaceæ*; dioecious, the male flowers consisting of a 4-parted perianth and four stamens; the female of a 2-3 cleft perianth, and a germen with four styles; the perianth hardening around the fruit as it ripens; the fruit an achénium.—**COMMON SPINACH**, or **GARDEN SPINACH** (*S. oleracea*), is in general cultivation for the sake of its young leaves, which are a favorite and wholesome vegetable, either prepared by boiling, or by frying with a little butter. Two very distinct varieties are cultivated: **PRICKLY SPINACH**, which has the leaves somewhat triangular and arrow-headed, and the fruit rough with prickly-like projections; and **SMOOTH SPINACH**, or **ROUND SPINACH**, (*S. glabra* of some botanists), with the leaves more round and blunt, and the fruit smooth. **SPINACH** is an annual. Its stem rises to the height of from 2 to 4 ft.; the male flowers are in long spikes, the female in clusters close to the stem. After the stem begins to be developed, the leaves become bitter, and unfit for use. This bitterness appears also at an earlier period in dry weather, or in poor soil; and the more luxuriantly that Spinach grows, the better it is. It is sown in spring, and is ready for use in a very short time; or it is sown in autumn, thinned out, and used early in spring. The smooth Spinach is very generally preferred for the former purpose, and the prickly kind for the latter; but a somewhat intermediate variety, called Flanders Spinach, is now often used for both, being particularly esteemed for the large size of its leaves. The native country of Spinach is not well known, but is believed to be some part of Asia, as the plant was introduced by the Arabs into Spain, and thence diffused over Europe. Another species (*S. tetrandra*) is cultivated, and much esteemed, in India. The name of Spinachis also given to a number of other plants of very different botanical characters, but which have the same bland and nutritious qualities, and are used in the same way.—**NEW ZEALAND SPINACH**

is *tetragonia expansa*, a plant of the natural order *mesembryaceæ*, sub-order *tetragoniæ* (nat. ord. *tetragoniaceæ* of Lindley), a trailing, succulent annual, spreading widely over the surface of the ground, and producing a great abundance of stalked ovate-rhomboid leaves. The young stems and leaves of this plant are much used in New Zealand, and have now come into very general use also in other parts of the world, as a kind of spinach. It is cultivated in the middle and s. of Europe and in Britain, succeeding well even in Scotland with the slightest aid of a hot-bed in spring.—PATIENCE DOCK, or GARDEN PATIENCE (*rumex patientia*; see DOCK), is called in Germany ENGLISH SPINACH, and was formerly much cultivated in England, but is now neglected.

SPINAKER. See YACHT.

SPINAL COLUMN, or **SPINE**, **THE**, is the most important and characteristic part of the skeleton of the highest animal sub-kingdom, which includes mammals, birds, reptiles, amphibians, and fishes. In each of these classes it is composed of a series of bones placed one above, or in front, of another, and called the *vertebræ*; and hence, these animals, having this distinguishing characteristic in common, are all included in the term *vertebrates*. The *vertebræ* vary greatly in number in different animals, and even in members of the same class, and the number have no apparent relation to the other organs of the animal. Moreover, in their shape, they differ extremely, even in different parts of the same spine, in accordance with their special functions. In man, the number of *vertebræ* which collectively form the spinal column is 7 in the neck (cervical *vertebræ*), 12 in the back (dorsal *vertebræ*), 5 in the loins (lumbar *vertebræ*), all of which are capable of being detached from one another, and are termed *true* *vertebræ*; and 5 *vertebræ* ossified together, and forming the sacrum, and 4 or 5 similarly united forming the termination of the column, and constituting the bone called the coccyx, which are known as *false* *vertebræ*. However long or short the neck may be, every mammal has 7 cervical *vertebræ*, excepting the three-toed sloth, which has 9, and the sea cow, which has 6. In the other regions of the spine no such law exists. Each *vertebra* is attached to the two between which it lies by numerous strong and more or less elastic ligaments, and between each pair of *vertebræ* there is interposed a lenticular disk of fibro-cartilage, which acts as a buffer. By these arrangements the spinal column is rendered highly elastic, the communication of jars or shocks is prevented, and a very considerable general range of movement permitted, although the motion between any two adjacent *vertebræ* is slight. The elasticity of the column is further increased by the component *vertebræ* being arranged in curves, instead of being placed perpendicularly. The curves should be exactly in the antero-posterior direction, any well-marked lateral deviation from the perpendicular being abnormal; but a very slight lateral curvature with the convexity to the right may often be detected in the upper and middle parts of the back, and is supposed to be dependent on the more frequent use and greater strength of the right arm as compared with the left. From their position they are termed the cervical, dorsal, lumbar, and pelvic curves. The dorsal and pelvic curves have their concavities in front, and thus enlarge the spaces in which the thoracic and pelvic viscera are contained; the two other curves are convex anteriorly, and thus afford support to the parts above them. The upper three curves are so arranged that their chords are in the same vertical line in the erect position of the body, and this vertical line corresponds with the line of gravity of the head. The cause of these curves is to be sought for partly in the shape of the vertebral bodies, and partly in that of the intervertebral substance. Among the uses of these curves it may be mentioned (1) that they enable the spine to bear a greater vertical weight than it could otherwise maintain; it is calculated that nine times as great a vertical force is required to bend it as if it had been straight; (2) that they facilitate the movements of the body, especially in the act of running; and (3) that they are so disposed as to protect the cord in movements of the spine. Similar curves are seen in the spine of other mammals, though the degree of flexure is liable to great deviations. The lumbar curve, which has especial reference to the erect position, is always much less marked than in man.

The vertebral canal formed by the apposition of the spinal foramina, or neural arches (see SKELETON), and containing and protecting the spinal chord, varies in its size at different parts of the column. It is largest in its antero-posterior diameter in the neck and loins (measuring at the last lumbar *vertebra* $\frac{3}{4}$ of an inch), where the antero-posterior movements of the spine are greatest, and where the cord is least closely attached to the *vertebræ*; while in its lateral diameter it is greatest at the atlas, where it measures nearly an inch and a half. A transverse section of the canal is nearly circular through the greater part of the back. The intervertebral foramina through which the nerves emerge vary in shape and position in different parts, but are always of sufficient size to prevent injurious pressure on the nerves during movement of the spine; and in the dorsal region, which is the ordinary seat of angular curvature, the nerves are so protected by bony arches that they may escape injury, even when the bodies of several dorsal *vertebræ* have been destroyed by ulceration.

SPINAL CORD or **MARROW**, **THE STRUCTURE AND FUNCTIONS OF.** The spinal cord is that elongated part of the cerebro-spinal axis (see NERVOUS SYSTEM) which is contained in the spinal canal from the *foramen magnum*, at the base of the skull, superiorly, to the first or second lumbar *vertebra* inferiorly, where it merges into the *filum terminale*, which extends to the lower end of the sacral canal, and in no way differs structurally

rally from the proper spinal cord, except that no nerve-roots are connected with it. The membranes by which it is protected from danger, and kept in its proper position, are described in the article NERVOUS SYSTEM. Its length varies from 15 to 18 in., and it presents a difference in its diameter in different parts, there being an upper or cervical, and a lower or lumbar enlargement. In form it is a flattened cylinder. It is almost completely divided, along the median plane by an anterior and posterior fissure, into two equal and symmetrical parts. The anterior fissure is more distinct and wider at the surface than the posterior fissure, but it only penetrates to about one-third of the thickness of the cord, while the posterior fissure extends to about half the thickness of the cord. The two halves are hence only united near the center by a commissural band, which is traversed by the "spinal canal" extending downward from the fourth ventricle (see BRAIN), and about one-hundredth of an inch in diameter. A posterior and an anterior lateral furrow (two shallow depressions, the latter being scarcely perceptible) further divide each half of the cord into a posterior, a lateral, and an anterior column; these two furrows corresponding with the lines of attachment of the posterior and anterior nerve-roots. The separation of the antero-lateral columns into the "anterior" and the lateral columns is made more obvious internally by the mode in which the gray or vesicular nervous matter (described in the article NERVOUS SYSTEM) is arranged in relation to the white or fibrous matter. Although the distribution of the gray matter differs considerably in different parts of the cord, it usually presents in a transverse section the form of two somewhat crescent-shaped masses, whose convexities are turned toward each other, and are connected by the gray commissure, while their cornua are directed toward the surface of the cord; the posterior peak on each side nearly reaches the posterior lateral furrow, while the anterior, though the larger cornu, does not approach quite so near the surface at the assumed anterior furrow. The enlargement of the cord in the cervical and lumbar region, where the great nervous plexuses are given off, is chiefly due to the increase, at those points, of gray matter, which is comparatively deficient in the interval between them. The white substance seems to increase regularly from the lower to the upper part of the cord; and this fact, as Dr. Carpenter remarks, seems to indicate the probability that the longitudinal columns serve (as formerly supposed) to establish a direct connection between the encephalic centers and the roots of the spinal nerves. Careful microscopic investigation has revealed the fact that the root-fibers of the spinal nerves run two very distinct courses in the substance of the cord; the first *transverse*, and the second *longitudinal*. The transverse fibers traverse the cord horizontally or obliquely, and appear to pass out in the other set of roots connected with the same segment, either on its own or on the opposite side of the median fissure; while the longitudinal fibers in part connect the posterior roots directly with the posterior column without passing into the vesicular matter, but for the most part enter the gray matter, and emerge from it into the posterior column, or into the posterior part of the lateral column of the same or the opposite side. How far these longitudinal fibers run up or down the cord, is undecided. It is probable that *some* of them are longitudinal commissures, serving to connect the nerve-roots of one segment of the cord with the vesicular matter of another above or below it, and it is possible that *all* are of this character, in which case the spinal cord will be the real center of all the nerve-fibers connected with it.

In considering the functions of the spinal cord, we have to regard it in two distinct points of view—viz., in the first place, as a *conductor* of nervous force between the nerve-trunks and the brain; and in the second place, as an *independent nervous center*. As a mere *conductor* of nervous force, its functions and behavior are the same as those of a nerve-trunk; for, as Dr. Carpenter observes: "If it be divided, all the parts of the body which are solely supplied by nerves coming off below the point of section are completely paralyzed, as far as regards sensibility and voluntary movement; no impressions made upon them having the least power to affect the consciousness, and no exertion of the will being able to determine contraction of the muscles. This state of *paraplegia*, which may be experimentally induced in animals, is frequently exhibited in man, as a result of injury or of disease that seriously implicates the spinal cord; and as it has been shown that among the lower animals complete reunion of the cord may take place after complete division, as indicated by the entire restoration of its functional powers, and the complete reintegration of its structure, so have we reason to believe that a similar regeneration may take place, to a considerable extent, in man, this being marked by a gradual return of sensibility and power of voluntary movement in the lower limbs, which had been at first completely paralyzed."—*Human Physiology*, 6th ed., pp. 529-30. There can be little doubt that the gray matter is essentially the conductor of *sensory* impressions, for if the anterior, posterior, and antero-lateral columns are divided as completely as possible, the gray substance remaining uninjured, the sensibility of the parts below is unaffected; while, conversely, if the gray substance is divided, while the white columns remain uninjured, sensibility is almost totally extinguished. M. Brown-Sequard, whose researches on the nervous system are of the highest importance, has shown that the central portions of the gray substance are the most effective in the transmission of sensation. He likewise brings forward strong evidence to prove that there are special conductors in the spinal cord for the sensations of touch, pain, temperature, and muscular contraction, none of which can convey other sensations than their own. Notwithstanding its singular power

of conducting sensory impressions, the gray substance is itself insensible. Among his other remarkable discoveries in connection with this subject, Brown-Sequard has found, that on dividing one-half of the spinal cord of an animal, not only is anæsthesia (or loss of sensation) established on the opposite side of the body, but there is also produced a state of hyperæsthesia (or exalted sensibility) on the same side, which begins to appear a few hours after the operation, and continues in dogs for about 20 days, in cats about 14 days, and in guinea-pigs for many months, after which the sensibility falls below its usual standard. With regard to the conduction of *motor* impulses, there is great uncertainty. Considerable differences have been shown to exist in the position of the motor tracts in different parts of the cord, and Brown-Sequard concludes from his experiments on the effects of section, that while in the dorsal region, all parts, except the posterior columns, are employed in the conveyance of the orders of the will to the muscles, in the upper part of the cervical region, most of these conductors are in the lateral columns and in the gray substance between these and the anterior column.

We have now to consider the spinal cord as an *independent nervous center*. The simplest, and, at the same time, the most decisive evidence of the independent power of the spinal cord, is derived from the motion exhibited by the limbs of animals when irritation is applied to them after section of the cord at some point above the entrance of their nerves; the fact that these movements are reflected through the cord, and do not result from direct stimulation of the part irritated, being shown by their complete cessation when the nerve-trunks are divided. Thus, if a frog be pithed by dividing the cord between the occipital foramen and the first vertebra, an unusual convulsion takes place while the knife passes through the nervous center; but this quickly subsides, and if the animal be placed on the table it will resume its ordinary position. It is quite unable to move by any voluntary effort; but if a toe be pinched, the limb is instantly drawn up, and seen to push away the irritating agent, and then draw up the leg again to the old position.

From these and other experiments, we may conclude (1) that the spinal cord *in union with the brain*, is the instrument of sensation and voluntary motion to the trunk and extremities; and (2) that the spinal cord may be the medium for the excitation of movements, *independently* of volition or sensation, either by direct irritation of its substance, or by the influence of a stimulus conveyed to it from some surface of the trunk or extremities by its nerves distributed upon that surface.

SPINAZZOLA, a city of southern Italy, in the province of Bari, 40 m. s.e. of Foggia. Pop. '81, 10,353. The chief productions are wine and oil. S. was birthplace of Pope Innocent XII.

SPINDLE TREE, *Euonymus*, a genus of plants of the natural order *celastraceæ*. This order contains about 260 known species, all small trees or shrubs.—The genus *euonymus* has a lobed capsule, and seeds surrounded by an aril, which in some of the species is remarkable for its brilliancy of color. The common spindle tree (*E. Europæus*), a native of Britain, chiefly of the southern parts, and of great part of Europe, is very ornamental when in fruit, and its aril is of a fine orange color. It is a shrub rather than a tree. The wood is hard and fine-grained. It is used for the finer articles of turnery, and for skewers. It was formerly used for making musical instruments and for spindles, whence the name of the shrub. In Germany, the shoots are bored for tubes of tobacco-pipes. Charcoal made of it is much valued for crayons.

SPINE, or **THORN**, in botany, is a sharp-pointed projection of the wood of a stem or branch, and essentially differs from a prickle (q.v.) in being connected with the wood, and covered with bark. A spine is, in fact, a branch arrested in its growth and modified. In some trees and shrubs, as in the sloe, branches which bear leaves often terminate in the form of a spine. Cultivation, or whatever tends to increase the luxuriance of a plant, diminishes the tendency to produce spines. The name spine is also given to the sharp extremities of the midrib of leaves, and to the sharp angular projection of the margin of hard leaves, as in the holly. In some plants, the stipules are metamorphosed into spines.

SPINE, CURVATURE OF THE. There are two perfectly distinct forms of curvature, viz., **LATERAL CURVATURE**—arising from weakness of the bones, ligaments, and muscles, and fearfully common in girls of the middle and upper classes, between the ages of 10 and 16—and **ANGULAR CURVATURE** (frequently known as **POTT'S CURVATURE**, or **THE MALADY OF POTT**, in consequence of that eminent surgeon having been the first to describe its true nature), which consists of caries of the bodies of the vertebræ, and is by far the more serious affection of the two.

"*Lateral Curvature, or Distortion*, denotes deformity of the bones of the spine and chest; with corresponding change of the structure in relation to them. It is called 'lateral,' from the spine being curved sideways; and to distinguish it from 'angular' deformity, in which the spine is directed from behind forward, owing to excavations in its forepart from caries." The above definition is taken from Mr. Shaw's article on this affection in Holmes's *System of Surgery*, vol. iv. p. 844, an article from which we have

borrowed freely in relation to the symptoms and causes of the disease. The first thing that commonly attracts attention is a projection of one scapula, or an elevation of one shoulder, generally the right; the right shoulder and right side of the chest being unnaturally high and rounded, while on the left side, the shoulder is depressed, and the side of the chest concave. On examination, the spine is found to have acquired a spiral appearance, "not unlike what might have been produced if it had been taken, when soft, at both ends by the two hands, and twisted as a washerwoman wrings a wet cloth."—Shaw, *op. cit.* In advanced stages of the distortion, the dorsal curve increases abruptly to such an extent as to render it angular, the attending contortion being similarly abrupt. This condition gives rise to various changes, including a *humped* appearance, a great displacement of the ribs, a diminution of the cavity of the chest, and a proportionate wasting of the lung. In consequence of these physical changes, the patient can no longer walk in a simple and natural manner, but exhibits a halting, jerking, awkward gait.

The following may be noticed amongst the principal causes of lateral curvature: 1. The suppleness of the spine in the young, its structures being then more gristle than bone, and the column virtually immature. 2. Weakness of the muscles, which are seldom properly exercised in girls of the age and class in which this disorder occurs. This muscular debility is usually followed by deterioration of the bones and their ligaments, and this, apart from other obvious and direct bad effects, tends to make all the component parts of the spine—vertebræ and articulations—more prone to yield to the superincumbent weight, and to become distorted. These evil results are increased by prolonged stooping. When we enter a school, shortly before the breaking up of the class, we usually find most of the pupils standing or sitting in a tired lounging position. They are instinctively relieving the pain of over-fatigue by throwing the weight on the insensible fibrous structures, and thus relieving the aching muscles. When such attitudes are long indulged in, the ligaments undergo a process of over-stretching, and a general looseness of the vertebral joints is the result. By standing on one leg, or, more correctly speaking, by throwing all the weight of the body on one foot, the body is kept upright with the least possible expenditure of muscular power. Hence, a weak and fragile girl is induced to adopt this position. Too long indulgence in this habit will, to a certainty (for anatomical reasons, into which we have not space to enter), aggravate existing curvature, and induce it, if it did not pre-exist.

However slight a curve in the spine of a young girl may be, it ought to be deemed of importance; for when the column inclines laterally even to a slight degree, the superincumbent weight ceases to be supported on the line of the vertical axis, and falls on the oblique processes of the side to which she leans; and these processes becoming rapidly diminished in length by absorption, induced by this abnormal pressure, general distortion rapidly commences. With regard to the final issue of a case, distortion beginning at the age of 10 is more dangerous than at 14, because the disease runs a more rapid course in the younger cases. A cure is, for the same reason, more easily effected in the younger patient. If the patient's age be beyond 16, little can be done beyond checking the further progress of the deformity.

Before discussing the treatment of these cases, it is necessary to say a word regarding an important preventive measure. When a girl is defective in muscular power, disinclined to take exercise, and prone to distortion of the spine, the sitting position does not afford her rest, in consequence of the great efforts she has to make in order to keep the body erect. A patient in that condition will derive benefit from being obliged to lie for two or three hours daily, at divided intervals, on a sofa or board. When the deformity has actually occurred, gymnastic exercises suggested by the medical attendant will not unfrequently, when continued for some time, have the effect of loosening the connection of the bones, of facilitating their falling into their proper places, when extension is employed, and of restoring to the spine a portion of its lost suppleness. Mr. Shaw suggests the following simple plan for attaining the same end: "Let the patient lie on one side, with a firm cylindrical pillow, 6 in. in diameter, placed under the gibbosity of that side, and let her rest her weight on the pillow: the effect will be to counteract and reverse the curve. The same may be done alternately on the two sides. The posture may be continued each way for a quarter of an hour at a time, and be repeated twice or thrice daily."—*Op. cit.*, p. 858. There are two methods of extending the curved spine, viz. (1), by stretching the body while the patient is recumbent; and (2) by letting the patient remain upright, and using spinal supports. As each method has its own advantages, a combination of them will often afford the best results. The chief objections to the former are the necessary confinement, comparative seclusion, and interference with the routine of study. Any mode of treatment with the view of producing extension of the spine must be continued for months in order to be of any avail. It would be altogether out of place to notice in this article the various extending beds, apparatuses for exercise, and different kinds of spinal supports that have been devised by surgeons and anatomical mechanicians, and we will merely observe that mechanical supports must be tried with great caution. They are always more or less irksome to bear, and if they are not doing good, are almost sure to be doing harm. On this subject, the reader may consult Heather Bigg's work entitled *The Spine and Upper Extremities*.

Angular curvature consists, as already mentioned, of caries of certain vertebrae, which first consumes the bones and fibro-cartilages, and subsequently excites a discharge of pus. The first symptom of this affection is the appearance, at the seat of the caries, of a prominence of one or more of the spinous processes. This "growing out" of the back, as patients frequently term it, is due to the destruction of a portion of the column. In an advanced stage the spinal ridge will stand out prominently, the knob of each process being distinctly visible; and finally, a distinct angular projection is developed. The consequences of this disease are thus summed up by Druitt: "1. In favorable cases the diseased bones collapse, and are ankylozed; abscesses, if they form, are healed, or their matter is absorbed, and the patient recovers in two or three years, with more or less deformity, which is, of course, incurable. 2. In some fatal cases the patient dies suddenly from two or three of the diseased vertebrae giving way, and crushing the spinal cord; or from dislocation of the odontoid process, owing to ulceration of its ligament; or from the bursting of abscesses into the spinal cord; or from their bursting into the pleura or peritoneum; but more frequently death is caused by slow irritation and exhaustion, consequent on the formation of psoas or lumbar abscesses."—*The Surgeon's Vade mecum*, 8th ed. p. 348. The most essential point in relation to treatment is rest, and the most effectual method of arresting motion between the diseased vertebrae, and of keeping them at rest is by placing the patient in a recumbent position on his back. If possible, an invalid bed should be procured, provided with contrivances for enabling him to lie upon it, day and night, without rising. Local counter-irritants, such as compound tincture of iodine, are often useful; and good diet, backed, if necessary, by cod-liver oil and tonics, must be prescribed. In conclusion, sufferers from any form of real or suspected spinal disease are earnestly warned to avoid the numerous quacks, whether in or out of the medical profession, who have taken up the spine as a specialty.

SPINEL, a mineral allied to corundum, consisting chiefly of alumina, with smaller proportions of magnesia, silica, and protoxide of iron. It occurs in crystals, which are often octahedral, and is chiefly found in Ceylon and Siam. Its colors are various; red, blue, green, and black. It is much prized as a gem; red spinels are commonly called rubies; the *balas ruby* is a rose-red spinel, and a violet-colored spinel is known as *alaman-dine ruby*.

SPINET (Ital. *spinnetta*), an old-fashioned stringed musical instrument with a keyboard, smaller and weaker than the harpsichord, and, like it, one of the precursors of the piano-forte. Each note had but one string, which was struck by a quill jack acted on by one of the finger-keys. The strings were placed horizontally and nearly at right angles to the keys, as in the square pianoforte; and the general outline of the instrument nearly resembled that of a harp laid in a horizontal position, with the keys occupying the position of the sounding-board; on which account the spinet, when first introduced, was called the couched harp.

SPINK, a co. in e. S. Dakota, drained by the Dakota river; 1505 sq.m.; pop. '90 10,581. The surface is uneven and the soil is fertile, furnishing good pasturage. Co. seat, Redfield.

SPINNER, FRANCIS ELIAS; b. N. Y., 1802; learned several trades, and was afterwards a merchant. He was auditor and deputy naval officer of the port of New York, 1845-49, a democratic member of congress, 1855-57, and afterward a republican member and chairman of the committee on accounts. He was treasurer of the United States, 1861-75. In the latter year he was an unsuccessful republican candidate for comptroller of New York state. His services as treasurer were of great value. He died 1890.

SPINNING is the art of combining animal and vegetable fibers into continuous threads fit for the processes of weaving, sewing, or rope-making. The most primitive spinning apparatus is the spindle and distaff, representations of which are to be seen on the earliest Egyptian monuments. The distaff was a stick or staff upon which a bundle of the prepared material was loosely bound, and which was held in the left hand or stuck in the belt; the spindle was a smaller tapering piece to which the thread was attached. By a dexterous twirl of the hand the spindle was made to spin round and at the same time recede from the spinster, who drew out between the forefinger and thumb of the right hand a regular stream of fibers so long as the twisting of the spindle lasted. It was then drawn in, the new length of thread wound upon it, and the operation was renewed. An obvious improvement on this was to set the spindle in a frame and make it revolve by a band passing over a wheel driven either by occasional impetus from the hand or by a treadle; this constituted the *spinning-wheel*, which is said to have been invented in Nuremberg as recently as 1530. In the spinning-wheel in its most improved form, and as usual for flax, a bobbin or "pirn," with a separate motion, was placed on the spindle which had a bent arm—a flyer or flight—for winding the yarn on the bobbin. The spindle and bobbin revolved at different rates, the revolutions of the spindle giving the twist, and the difference of the rate causing the winding on. The two-handed wheel had two spindles and pirns a little apart, with the distaff or "rock" stuck into the frame between them, and the spinster produced a thread with each hand. The spinning of flax on such wheels for the manufacturer was an important branch of domestic industry in the northern counties of Scotland as late as 1830, if not later.

Neither the spinning-wheel nor the hand could spin more than one, or at most two threads at a time, and therefore, with the rapid increase of population, and the improvements made in the process of weaving (q.v.), they became quite inadequate to supply the demand for yarn: but an accident, it is said, about the year 1764, led to an invention by which eight threads could be spun at once; and this was soon improved upon until 80 could be produced as easily. This was the invention of the *spinning-jenny* for cotton-spinning, by James Hargreaves, at Stankhill, near Blackburn in Lancashire. In this machine, a number of large reels of cotton formed into a thickish coil, called a *roving*, were set on upright fixed spindles, and the ends of the rovings were passed between two small movable bars of wood placed horizontally and under the control of the spinner, who could thus make them press more or less on the roving, and consequently increase or decrease the draw upon it from the spinning spindles, which were set in a row at the other end of the frame, and all capable of being set in motion simultaneously by the wheel. The success of the spinning-jenny was considerable, but its history has been too often told to be required here; and even previous to its invention, a better idea had been started and acted upon by others, and was afterward brought to such perfection, that the invention of Hargreaves soon passed into obscurity.

In order to understand the operations of spinning as now practiced, and as improved by the invention alluded to, it is desirable, in this place, to say a few words upon the preparation of the fibers for the process of spinning. In the first place, if wool or cotton,

FIG. 1.

the "blower" or "opener," and being put into a shaft, is there acted upon by a stream of air violently driven in by machinery, which blows it forward, removes extraneous matters, and so separates the fibers that they pass out at the other end in an exceedingly light flocculent state, and ready for being formed into *laps*. This operation consists in laying the material very equally on an endless apron made of small bars of wood, and of the width of the frame of the machine in which they are placed. This apron (*a*, fig. 1) passes round two rollers, placed at a little distance apart, as in fig. 1, *b*, *e*, the rollers being moved by machinery. The arrows indicate the direction in which the apron moves; and as the operator covers its entire surface with a thin layer of the fiber, it passes under under the roller *d*, and is taken on to the roller *e*, in the form of a compressed layer of cotton or wool, called a *lap*. When the roller *e* is full, it is removed, with its lap *f*, to make way for another. Much care is taken in weighing out and distributing the material of these laps, because upon this first operation the ultimate size of the yarn depends.

The laps are taken to the *carding-machine*, consisting of a series of cylinders revolving in a frame, and placed so close together that they almost touch each other. Each cylinder is covered with a coating of fine steel wire points, which are stuck in leather, or some other flexible material, and are technically called *cards*. The production of these cards by machinery is in itself a marvel, and the automatic machines for making them are wonderfully effective. Each piece of wire is bent and put through two holes in the leather so as to form two points on the other side, and these are slightly bent all in one direction. There are many variations upon this arrangement of the wires, but the general principle is the same in all. The machine for making the cards cuts the wire to the right lengths, bends them, pierces the holes in the leather, inserts the wires, and finishes by giving them the slight sloping direction which is essential.

The lap is made of the same width as the cylinders of the card-machine, and is so adjusted that, as it unwinds from its roller, it passes in between a pair of the carding cylinders, the steel wire teeth of which seize hold of the individual fibers, and drag them in one direction until they are caught by other cylinders, and so carried from one to another, always being pulled in a straight direction until they are laid as nearly as possible side by side, and are given off in a thin cobweb-like film at the last cylinder, where it is prevented from continuing its journey round the cylinders by a small bar of metal called the *doffer*, which, with a gentle and peculiar motion, removes it from the cylinder. The film of fiber is of the same width as the cylinder of the carding-machine, but it is gathered together by the operator, who passes it through a smooth metal ring, and

between two small polished rollers, the revolutions of which carry it forward and deposit it in a deep tin can in the form of a loose untwisted column of cotton or wool, about an inch in thickness, which is called a *sliver*. A small portion of this arrangement is shown in fig. 2, which represents a carding-machine with only two carded cylinders, *a* and *b*; they are, however, much more numerous. There is also a concave piece of carding, *c*, which was formerly much used, but has lately given way to additional cylinders, but it makes the action more apparent in a drawing; *d* is the lap drawn on by the action of the two small rollers *e, e*, which slightly press it as they revolve. It is quickly distributed all over the surface of the large cylinder *a* by means of its numerous wire-teeth; and as it passes the roller *b*, the teeth of which move in an opposite direction, as indicated by the arrows, the fibers are caught off the large, and are carried round the small cylinder until they reach *f*, where they are stripped off by the doffer *g*, and are passed through the ring *h*, and the rollers *i, i*, into the tin receiver *k*. The sliver is now in the first stage of spinning; it has next to be drawn out very gradually until it is not thicker than a quill; and, in drawing it out, the operator gives it a very slight twist, still leaving it so loose in structure that it will break with a slight touch; in this state it is called a *roving*; and it was at this stage that the spinning-jenny began to operate upon it. The rovings, which were wound as they were drawn upon large reels, were unwound by the machine, and were still further drawn out and firmly twisted and wound on to spindles or cops, the drawing being regulated by the pressure of the wooden bars of the jenny, which was within reach of the operator's hand.

FIG. 2.

The *throstle-machine*, patented by Arkwright in 1769, had for its object the drawing of the rovings through a succession of pairs of rollers, each pair in advance of the others, and moving at different rates of speed. The first pair receive the sliver, compress it, and pass it on to the second pair, which revolve at a greater speed, and thus pull it out to exactly the number of times greater length that their revolutions exceed those of the other pair—in number it is usually eight times—and as the first roving is passed through a second, third, and sometimes fourth machine, the finished roving is 32 times longer than the sliver. As the roving issues through the last rollers of each machine it is received on *spools* or *reels*, calculated to hold a given quantity; and these are transferred to the *spinning-frames*, which resemble the *roving-frames*. Here the roving takes the place of the sliver; and, as it unwinds from the spool, is drawn through successive pairs of rollers, moving as before at different rates, each succeeding pair faster than the backward ones, so that the roving gets thinner and thinner, until the tenuity is carried as far as desirable. It is then carried on to a spindle which revolves with great rapidity; and, by means of a simple arrangement, is made both to twist the thread and wind it on the spindle ready for the weaver.

This system produces too great a strain upon the thread in its progress to admit of its being drawn so fine as is wanted for many purposes, and this led to the invention of the *mule-jenny* by Crompton (q.v.) in 1779, which has a traveling frame upon which the spindles are set. This frame is now made long enough to carry hundreds of spindles, and it gently draws out and twists the thread after it leaves the last pair of rollers; and when it has reached its limits—now several yards, but in Crompton's time only five feet—it rapidly returns, winding up the spun thread on the spindles as it goes back. These machines are now applied, with various necessary modifications, to cotton, wool, flax, silk, and other textile materials, and the effect they have exerted upon our manufactures is more wonderful than anything in the whole history of commerce. Previous to the invention of the mule, few spinners could make yarn of 200 hanks to the pound (the hank being always 840 yards). At the same time, the natives of India were weaving yarn of numbers ranging between 300 and 400. Now, however, in England they have reached such extraordinary perfection that Messrs. Houldsworth of Manchester have succeeded in making No. 700, which was woven by the French firm, Messrs. Thivel & Michon of Taware, and others far too fine to weave, the greatest tenuity reached being 10,000, a pound of which would reach 4770 miles. This was made to test the perfection of the machinery, but was of no practical value.

The most modern improvements in spinning are in the machines of Messrs. Platt & Co., of Oldham, which combine all the operations of carding, roving, and spinning in one machine. These and similar machines have now come almost into universal use for cotton and wool.

SPINOLA, AMBROSIO, Marquis de, 1569–1630; b. Italy; served in the Spanish navy, against the English and Dutch. In 1602 he led a force of 9000 veterans to the Neth-

erlands against Maurice of Nassau. Made chief commander of the Spanish army there; he forced Ostend to surrender in 1604, after a siege of three years. He continued his operations against Maurice till the truce of 1609, when he took command of the Spanish troops in Germany. He captured Jülich in 1622, and Breda in 1625. He afterward commanded the Spanish army in Italy.

SPINOZA, BARUCH (= *Benedict*), one of the greatest philosophers of modern times, was born at Amsterdam Nov. 24, 1632. His parents, rich Portuguese Jews, had their son diligently instructed in the Bible and its commentaries, and the Talmud. But after having mastered both, and imbibed the philosophical spirit of such commentators as Aben Ezra, he was allowed—the more readily that his sickly constitution unfitted him for a commercial career—to devote himself entirely to a life of study. Physical sciences and the writings of Descartes, to which he turned first of all, very soon drew him away from the rigid belief and practices of the synagogue; and Saul Levi Morteira, his Talmudical teacher, who had built the fondest hopes upon the genius of his pupil, was the first to threaten him with the direst punishment if he did not retract the rank heresies that he began openly to utter. Spinoza, after a time, entirely withdrew from the community of his brethren, who formally excommunicated him. A fanatic even attempted to frighten him by an either real or feigned attack upon him as he left the theater one night. At that period, the young truth-seeker made the acquaintance of the young and beautiful daughter of Van den Ende, his master in Greek and Latin, and fell passionately in love with her, but was rejected. From that time forth, philosophy became the sole aim and object of his life. In accordance with the teaching of the sages of the Mishna, Spinoza had, apart from his studies, made himself master of a mechanical craft. He had learned the art of polishing lenses. This now became the means of his subsistence. Besides, he was also an expert in the art of design, and among a number of other portraits, he drew one of himself in the dress of Masaniello.

When 29 years old he left Amsterdam, and went to Rhynsburg, near Leyden, where he wrote the *Abridgment of the Meditations of Descartes*, with an appendix—the latter being the first cast, so to say, of his *Ethics*. The year following he removed to Voorburg, near the Hague, and shortly afterward, yielding to the solicitations of his, by this time, numerous friends, he removed to the Hague itself. The elector of the palatinate, Charles Lewis, next offered him a vacant chair at the university of Heidelberg, with full "liberty of teaching," provided he would not say aught to prejudice the established religion, i.e., Christianity; whereupon Spinoza declined the both lucrative and honorable professorship. His small pittance was enough to satisfy his wants. In a similar way, he refused generous offers made to him by wealthy friends, like Simon de Vries, who intended to bestow a large sum of money on him. All he could be prevailed upon to accept was a small annuity of a few hundred florins, the rest he persuaded his generous friend to bestow upon his (De Vries's) own brother. An offer of a pension, on the condition of his dedicating a work to Louis XIV., he rejected with scorn. His domestic accounts, found after his death, show that he preferred to live on a few pence a day, to being indebted to another's bounty. He died, 44 years old, on Feb. 21, 1677. Throughout his life of study, of abstemiousness, of bodily and mental suffering—for his constitution was undermined no less by consumption and overwork, than his sensitive mind was wrought upon by the violent severance of all natural ties of affection, to say nothing of the misery of occasional want and of perpetual persecution—no complaint ever passed his lips. Simplicity and heroic forbearance, coupled with an antique stoicism and a child-like, warm, sympathizing heart, were the principal attributes of him who was nicknamed epicurean and atheist by his contemporaries. It has well been said, that no man, perhaps, was more filled with religion than Spinoza, and that to be an epicure at the rate of twopence-halfpenny a day cannot be a very serious crime.

Respecting Spinoza's philosophical system, of which we can only give the very faintest of outlines here, it must be premised that it developed itself on the basis of Descartes. The latter had inaugurated a new epoch by his "reconstruction" of knowledge. Dissatisfied both with the dogma and the skepticism around him, he cleared the ground by first doubting everything, and then laying a new foundation by *Cogito, ergo sum* (I think, I therefore am). Spinoza, however, deeply struck both with the reasonings and conclusions of Descartes, took his "I think therefore I am" merely as a starting-point to prove more clearly the existence of God than Descartes did. The consciousness of man's own existence and of his imperfect state are not, he thinks, sufficient to solve the grand problem. He therefore assumes, first of all, three fundamental things, which he calls respectively substance, attributes, and mode. By substance he understands, like Descartes, that which needs nothing else to its existence; but, unlike Descartes, he assumed only one such substance—God. Yet this term is not to be understood in the ordinary sense, for Spinoza's God neither thinks nor creates. There is no real difference, he holds, between mind, as represented by God, and matter, as represented by nature. They are one, and, according to the light under which they are viewed, may be called either God or nature. The visible world is not distinct from him. It is only his visible manifestation, flowing out of him, who is the last fountain of life and essence, as a finite from the infinite, variety from unity—a unity, however, in which all varieties merge again. Extension and thought, which, with Descartes, had been two substances,

with Spinoza become "attributes;" that which the mind *perceives* as *constituting* substance. Extension is visible thought; thought is invisible extension. The relation between substance and attributes, Spinoza illustrates by the example of an object—colorless in itself, perhaps—seen through yellow or blue spectacles. And this explains the relation between body and mind, and the complete unity between them. The mind is the idea of the body—i. e., the same thing considered under the attribute of thought. The *modus* or *accidens* is only the varying form of substance. Like the curling waves of the ocean, they have no independent existence; nay, less than these are they things of reality; but they are simply the ever-varying shapes of the substance. Substance, thus, is the only really existing, all-embracing essence, to which belongs everything perceptible to our senses, and not perceptible. Thus every thought, wish, or feeling is a mode of God's attribute of thought; everything visible is a mode of God's attribute of extension. God is the "immanent idea," the one and all. "World" does not exist as world—i. e., as an aggregate of single things—but is one complex whole and one peculiar aspect of God's infinite attribute of extension. The variety we behold in things is a mere product of our faulty conceptions, particularly of, as Spinoza terms it, our "imagination," which perceives unity as a complex of multiplicity.

On these metaphysical speculations he founds his ethics, which he deduces in a mathematical form, after the method of Euclid. The chief doctrines are: the absence of free will in man—himself only a *modus* dependent on causes without, and not within him. Will and liberty belong only to God, who is not limited by any other substance. Good and evil are relative notions, and sin is a mere negative; for nothing can be done against God's will, and there is no idea of evil in him. Utility alone, in its highest sense, must determine the good and the evil in our mind. Good, or useful, is that which leads us to greater reality, which preserves and exalts our existence. Our real existence is knowledge. Highest knowledge is the knowledge of God. From this arises the highest delight of the spirit. Happiness is not the reward of virtue, but virtue itself; and this is to be attained by a diligent following in God's ways. Sin, evil, negation, etc., are merely things that retard and obstruct this supreme happiness.

Spinoza's system, pantheism or atheism, as it has been variously called, appears to be nothing but the most rigid, most abstract, monotheism that can be conceived by man. There is only substance, only God—nought else. It was not unnatural, however, that this system should be misunderstood either as materialism or as pantheism; seeing the word "substance," which, with Spinoza, means "existence," is, in ordinary language, associated with the idea of matter or body. Be this as it may, "this most iniquitous and blasphemous human invention," as it has been called for 200 years, has become the acknowledged basis of modern German philosophy; and pious theologians like Schleiermacher did not hesitate to apply the highest terms of "pious, virtuous, God-intoxicated," to Spinoza, who, we need not add it, never left Judaism, although he left the synagogue and its human formalities.

His principal works are—*Renati Descartes Principiorum Philosophiæ, Pars I. et II., more Geometrico Demonstratæ* (Amsterdam, 1663); *Tractatus Theologicus-politicus* (anonymous, 1670); the *Opera Posthuma*, edited in the year of Spinoza's death by Ludwig Meyer, contain: *Ethica Ordine Geometrico Demonstrata*; *Tractatus Politicus*; *Tractatus de Intellectus Emendatione*; *Epistolæ*; *Compendium Grammaticæ Linguae Hebrææ*. Several minor treatises are lost; but the lately discovered *Tractatus de Deo et Homine*, published in 1862, is a most valuable addition to our materials for tracing the development of Spinoza's system. The literature on the Spinozistic philosophy is very copious, especially in Germany. Spinoza's life has even been made by Auerbach the subject of two romances. The best editions of Spinoza's works are those of Paulus (1802-3) and Bruder (1843-46). See Pollock's *Spinoza* (1880).

SPIRÆA, a genus of plants of the natural order *rosaceæ*, and of the suborder *spirææ*, in which the fruit consists of five or fewer capsular carpels distinct from the calyx, and each containing 1 to 6 seeds. The genus *spiræa* has one or more follicular, many-seeded carpels. It contains a large number of species, natives of Europe, Asia, and America, herbaceous plants and low deciduous shrubs; of the herbaceous species, two are natives of Britain, DROPWORT (*S. Filipendula*) and MEADOW SWEET or QUEEN OF THE MEADOW (*S. Ulmaria*), both with interruptedly pinnate leaves and flowers in cymes. Dropwort is a native of dry upland pastures; it is tonic and fragrant; and its tubers, which are somewhat nutritious, are in Sweden ground and made into bread. Meadow sweet is well known for the powerful fragrance of its flowers. A fragrant distilled water is prepared from them. A North American species (*S. tomentosa*), called HARDHACK in the United States, is there used as a tonic and astringent. Many of the shrubby species are frequently planted for ornament.

SPIRAL, in geometry, is the name given to a class of curves which, during their gradual regression from a point, wind round it repeatedly. Their equations are generally expressed in terms of polar co-ordinates, and are all necessarily of the form $r=f(\theta)$, where θ never signifies a function of the angle, but the angle itself or a multiple of it. Several such curves have received distinguishing epithets, either on account of the properties they possess, or from their inventor; the chief of them are—the *equable spiral* or the *spiral of Archimedes*, whose equation is $r=a\theta$ and which, commencing at the origin,

circles round and regre-des from it with unvarying uniformity; the *hyperbolic* or *reciprocal spiral* ($r\theta=a$); the *logarithmic* or *equiangular spiral* ($r=ab\theta$); which recedes from the center or origin with a velocity increasing as the distance, and always cuts the radius vector at the same angle; etc.

SPIRAL VESSELS are those very delicate air-tubes in the cellular tissue of plants which run unbranched through the different parts of the plant, and whose walls are composed of fibers spirally or circularly twined. Spiral vessels are either *free*, when their windings are unconnected with each other, or *net-like*, when the windings are involved with each other in a net-like manner. If the free spaces between the convolutions in the latter are linear, they form *lined vessels*; but if they are point-like, they form *punctate* or *porose* vessels. Spiral vessels, whose walls are formed of distinct horizontal rings, placed simply one above another, are called *annular vessels*. Spiral vessels seldom occur singly, but are generally united by cells into bundles called vascular bundles. These vascular bundles are scattered in the stems of endogenous plants; but in the stems of exogenous plants they are arranged in one or more concentric circles. Among cryptogamous plants, the ferns alone (in the most extensive signification of the term) are provided with spiral vessels. All plants which have spiral vessels are called *vascular plants*, in contradistinction to *cellular plants*, whose substance consists of cells only.

Through the operation of what laws the spiral form is assumed by spiral vessels, is still unknown, although the question has naturally been regarded as having an intimate connection with the tendency to spiral structure manifested in plants, and even in some of those cryptogamous plants in which no true spiral vessels are found; a tendency which is observed not only in spiral stems, spiral tendrils, the spiral fibers of the elaters of *jungermannia*, and the like, but throughout the vegetable kingdom generally in the spiral arrangement of leaves and of the organs which are formed by the metamorphosis of leaves. The whole subject is an extremely difficult one.

SPIRE, a very acute pyramidal roof in common use over the towers of churches. The history of spires is somewhat obscure, but there is no doubt that the earliest examples of anything of the kind are the pyramidal roofs of the turrets of Norman date. Those of St. Peter's, Oxford, and Rochester cathedrals, are good specimens of circular and octagonal spires on a small scale. Spires of this early period are much lower than those of later date. The early English style has spires of acute form over the larger towers. They are generally what are termed broach spires, i.e., the slopes spring from the cornice of the tower without any parapet, and at the point where the square changes to the octagon there is a small set-off or separate roof. Sometimes the angles at top of towers were occupied with pinnacles or sloping masses of masonry, as at Bayeux cathedral, Normandy.

In the decorated style the spires were more enriched, with a parapet and pinnacles at the top of the tower, crochets on the angles, and enriched windows.

The spires of the perpendicular and flamboyant styles are still more enriched, with flying buttresses at the angles, etc. They are sometimes perforated, and the sides of the spire filled entirely with tracery. Such spires are common in Germany, those of Strasbourg and Frieburg on the Rhine being very fine examples. As in the later styles generally, the character and beauty of the spire give place to dexterity in masonry, and many examples exist of traceried spires more wonderful than beautiful. See **GOthic ARCHITECTURE**.

SPIRES. See **SPEYER**.

SPIRILLUM. See **COMMA BACILLUS**.

SPIRIT, a name of very general application to fluids, mostly of a lighter specific character than water, and obtained by distillation. Thus, the essential oil of turpentine is called spirit of turpentine. But in a stricter sense, the term spirit is understood to mean alcohol (q.v.) in its potable condition, of which there are very numerous varieties, deriving their special characters from the substances used in their production.

SPIRIT DUCK. See **GARROT**.

SPIRITO SANTO. See **ESPIRITU SANTO**

SPIRITUALISM. Under the head of **ANIMAL MAGNETISM**, an account is given, from the skeptical point of view, of some of those mysterious phenomena which, under the name of modern Spiritualism, have recently attracted so much public attention. It is proposed here to give a more complete account of these phenomena as they appear to those who hold that they are inexplicable by the commonly received laws of physics.

That these phenomena in their higher phases—as those of trance, healing by touch, and subjection to the thought and will of another mind—are intimately allied with those of mesmerism is obvious to all who have given any careful attention to them. Spiritualists, indeed, affirm that they differ only in this—that in the one case the operator is a mortal, in the other a disembodied human spirit possessing a spiritual body instead of a physical one. Those persons most readily susceptible to mesmeric influence generally prove to be the best mediums for spirit manifestation. Wherever mesmerism has been extensively practiced, it would seem that the ground has thereby been prepared

for the operators in the unseen world; and indeed human magnetism is not unfrequently resorted to for this express purpose. Many of the earliest and foremost advocates of Spiritualism in England have traveled to Spiritualism *via* mesmerism. As is fully shown in the correspondence of M. Billault and M. Deleuze, published in two volumes in 1836, the magnetists of France anticipated by at least half a c. the revelations of what is now known as "modern Spiritualism," which was as humble in its origin as other great movements recorded in history which have so largely influenced mankind.

In the village of Hydesville, New York state, lived Mr. John D. Fox and family, much respected by their neighbors as honest upright people. The two youngest children, Margaret, then twelve years old, and Kate, nine, were staying with their parents. Soon after they had taken up their residence here, in Dec., 1847, they began to hear knockings in the house, which toward the end of March increased in loudness and frequency. Mr. Fox and his wife got up night after night, lit a candle, and thoroughly searched every nook and corner of the house, but discovered nothing. When the raps came on a door, Mr. Fox would stand ready to open it the moment they were repeated, but though he opened the door on the instant, he could detect nothing, and no one was to be seen; nor could he obtain the slightest clue to the cause of these disturbances. But through all these annoyances Mr. and Mrs. Fox clung to the belief that some natural explanation of them could be found. Nor did they abandon this hope till the last night of March, 1848. Wearied out by a succession of sleepless nights, and of fruitless attempts to penetrate the mystery, the family had retired very early to rest; but scarcely had the mother seen the children safely in bed, and was retiring to rest herself, when the children cried out: "Here they are again!" The mother chid them, and laid down. Thereupon the noises became louder and more startling. Mrs. Fox called in her husband. The night being windy, it suggested to him that it might be the rattling of the sashes. He tried several, shaking them to hear if they were loose. Kate happened to remark that as often as her father shook a window-sash, the noises seemed to reply. Turning to where the noise was, she snapped her fingers, and called out: "Here, do as I do?" The knockings instantly responded. She tried, by silently bringing together her thumb and forefinger, whether she could still obtain a response. Yes! It—the mysterious something—could see, then, as well as hear! She called her mother: "Only look, mother," she said, bringing her finger and thumb together as before. And as often as she repeated the noiseless motion, just so often responded the raps. This at once arrested the mother's attention. "Count ten," she said; ten strokes were distinctly given. "How old is my daughter, Margaret?" Twelve strokes responded. "And Kate?" Nine! "What can all this mean?" was Mrs. Fox's thought. Who was answering her? Was it only some mysterious echo of her own thought? The answers to the next question she put seemed to refute this idea. "How many children have I?" she asked aloud. Seven strokes. "Ah!" she thought, "it can blunder sometimes." And then, aloud, "Try again." Still seven strokes as before. Of a sudden a thought crossed her mind: "Are they all alive?" she asked. Silence for answer. "How many are living?" Six strokes. "How many dead?" A single stroke; she had lost a child. Then she asked, "Are you a man?" No answer. "Are you a spirit?" It rapped. "May my neighbors hear if I call them?" It rapped again. Thereupon she asked her husband to call a neighbor, a Mrs. Redfield, who came in laughing. But her mirth was soon changed. The answers to her inquiries were as prompt and pertinent as they had been to those of Mrs. Fox. She was struck with awe; and when, in reply to a question about the number of her children, by rapping four, instead of three, as she expected, it reminded her of a little daughter, Mary, whom she had recently lost, the mother burst into tears.

Of course a knowledge of these things could not be kept secret. The news soon spread, and the utmost excitement prevailed in the little village and beyond it. Neighbors flocked in, and the house was besieged, and the time of the family wholly taken up with curious and eager visitors. Formal depositions appeared in more than one publication. The earliest of these, published April, 1848—a pamphlet of 40 pages—contains 21 certificates, chiefly given by the immediate neighbors. Most of the witnesses offer to confirm their statements, if necessary, under oath, and express their conviction that the family had no agency in producing these sounds.

It was found that these were more marked in the presence of Kate Fox, and in the hope of getting rid of these annoyances, Kate was sent on a visit to Mrs. Fish, a married sister, at Rochester. The only result being that, while the rappings did not cease at Hydesville, a new and more extended scene of operations was given them at Rochester, whither they followed Kate, and were found also to accompany her sister, and a girl who resided with them.

On one occasion a visitor suggested that the alphabet should be called over, to see if the sounds would respond to the required letters, and so spell out a communication. A shower of raps followed, as if to say: "Yes, that is what we want!" The first message so given, was: "We are all your dear friends and relatives." Then the name of "Jacob Smith," Mrs. Fish's grandfather, was given. Previous to the spiritual telegraphy thus commenced, the only mode of communication had been by asking questions, one rap being understood as an answer in the negative, three in the affirmative, and two, doubtful, or that the answer could not then be given. It was now asked that a signal should

be given when the alphabet was required; this was responded to by five strokes, which was henceforth understood as a call for the alphabet; and so a code of signals was instituted.

Similar demonstrations occurred about this time, independently, in the homes of some of the most respectable inhabitants of Rochester. At length it was communicated by the rapping that the facts should be given to the world, with a view to open up a more extended intercourse; and instructions were given as to where, how, and by whom this was to be done. There was much difficulty in getting the parties named to take the responsibility, and incur the discredit and ridicule of this step; but their scruples were at length overcome; and on Nov. 14, 1848, a public lecture, giving a simple narrative of the facts, was delivered in the Corinthian Hall, Rochester, to an audience of about 400 people. The rappings, as had been promised, were distinctly heard in all parts of the hall; and a committee was appointed by the audience to investigate the subject, and report at a subsequent meeting. The committee all agree that the sounds were heard; but they entirely failed to discover any means by which they were produced.

This result was very different to what had been confidently anticipated, and the dissatisfied audience, amazed at the failure, appointed a second committee, which it was expected would make such an investigation as could not fail to find out the trick; and when this committee, after the strictest investigation, only confirmed the judgment of its predecessor, the excitement became intense; and a third committee was appointed, consisting of those who had shown the most determined hostility to the reports of the previous committees, and who had expressed the utmost confidence in their ability to detect the imposition. It certainly was no fault of theirs that they did not. They resorted to every means their ingenuity could devise; but no fraud could be detected, no explanation given. The "mediums" were separated, and their friends were rigorously excluded from the sittings of the committee. They were unexpectedly removed, first to one house, then to another. A committee of ladies divested them of their clothing; feather pillows were placed under their feet; the stethoscope was applied to see that there was no movement of the lungs by which the sounds could be made. Under every condition imposed the obstinate raps came—on doors, floors, walls, ceiling; the place seemed alive with them. When this final committee, baffled and mortified, made known their failure, the meeting broke up in the greatest excitement and confusion. But the object was gained: the facts were reported and commented on in all the journals throughout the country.

Circles for investigation were now everywhere formed, and not only were the rappings obtained, but new phases of these strange phenomena were constantly developed. In *Forty Years of American Life*, by Thomas Low Nichols, M.D., we read: "Dials were made with movable hands, which pointed out letters and answered questions without apparent human aid. The hands of mediums, acting convulsively, and, as they averred, without their volition, wrote things apparently beyond their knowledge, in documents purporting to be signed by departed spirits. Their writings were sometimes made upside down, or reversed so as only to be read through the paper or in a mirror. Some mediums wrote with both hands at a time, different messages, *without*, as they said, being conscious of either. There were speaking mediums, who declared themselves to be the merely passive instruments of the spirits. Some represented, most faithfully, it was said, the actions, voices, and appearance of persons long dead; others, blindfolded, drew portraits, said to be likenesses of deceased persons they had never seen—the ordinary work of hours being done in a few minutes. Sometimes the names of deceased persons and short messages appeared in raised red lines upon the skin of the medium. Ponderous bodies, as heavy dining-tables and piano-fortes, were raised from the floor, falling again with a crash and jar. Tables on which several persons were seated were in like manner raised into the air by some invisible force. Mediums are said to have been raised into the air and floated about above the heads of the spectators. Writings and pictures were produced without visible hands. Persons were touched by invisible, and sometimes by visible hands. Various musical instruments were played upon without visible agency. Strange feats of legerdemain, as the untying of complicated rope-knottings in an incredible short time, astonished many. Voices were heard, which purported to be those of spirits. In a word, over a vast extent of country, from e. to w., these phenomena existed, or were said to exist, in hundreds of places, and were witnessed by many thousands of people—numbers of whom were of the highest credibility, and the mass of those persons whose testimony no one would think of impeaching in a trial of life and death."

Many theories were invented to explain these phenomena; they are now for the most part obsolete or forgotten. Each theory generally began by exploding its predecessors, and was in turn exploded by its successors. No sooner was a theory invented to explain one class of facts than another sprang up for which it made no provision, and to which it was manifestly inadequate. Not only did the flame spread, but sometimes the extinguishers caught fire; and those who at first were its opponents, ended as its advocates. The most obdurate materialists became convinced of a future life for man by the experimental evidence spiritualism supplied. For instance, Prof. Hare instituted a series of experiments intended to prove that the phenomena were wholly due to natural causes;

and the public, and men of science in particular, were surprised when, in place of this explanation, there appeared a large work with his name as its author, entitled *Spiritualism Scientifically Demonstrated*; and with diagrams of ingenious apparatus invented by him to test the genuineness of the phenomena. The Hon. J. W. Edmonds, judge in the supreme court of appeals for the state of New York, brought to bear upon the subject a mind trained by long judicial experience, and the careful sifting of evidence. He investigated with many different mediums, and took notes as carefully as though in court. To his great astonishment he found he was himself a medium, and under the title *Spiritualism* he published two large volumes, narrating his investigations, visions, and spiritual communications. His daughter, Laura, also became a medium, and under some foreign influence would sometimes answer freely in languages with which in her normal state she was wholly unacquainted.

Reports of these marvels soon crossed the Atlantic; but in England, for a long time, they excited little serious attention, and were generally received, not only with incredulity, but with ridicule and contempt. The visit to London of Mrs. Haydon, an American medium, in 1854, first excited any considerable degree of public interest in spiritualism. Many visited her, most of whom were puzzled, some ridiculed, a few were convinced. Among the latter were Robert Owen, the founder of English socialism, and Dr. Ashburner, the translator of Reichenbach, and the colleague of Dr. Elliotson in the establishment of the *Zoist* and of the Mesmeric infirmary. In 1855 a more remarkable medium came to England, Mr. Daniel Dunglas Home. The manifestations which occurred in his presence were soon the subject of newspaper controversy. From that time to this they have been seen and tested repeatedly by scientific and other witnesses of the highest credit and social position; and they made him a frequent and welcome guest at the Tuileries and at the courts of Berlin and St. Petersburg. A full account of his strange experiences is given in his autobiography, entitled *Incidents in My Life*. They include nearly the whole range of "manifestations" referred to in the important report of which we are about to speak.

In Jan., 1869, the London dialectical society appointed a committee "to investigate the phenomena alleged to be spiritual manifestations, and to report thereon." The committee invited evidence from all sides, and especially solicited the co-operation of scientific men, and resolved itself into sub-committees for experimental investigation and test. In July, 1871, the committee presented its report, with minutes of evidence, reports of *séances*, and other documents, making a volume of 412 large octavo pages. The committee state that "a large majority of the members of your committee have become actual witnesses to several phases of the phenomena, without the aid or presence of any professional medium, although the greater part of them commenced their investigations in an avowedly skeptical spirit." A synopsis of the evidence is also given as follows: "Thirteen witnesses state that they have seen heavy bodies—in some instances men—rise slowly in the air, and remain there for some time without visible or tangible support. Fourteen witnesses testify to having seen hands or figures, not appertaining to any human being, but lifelike in appearance and mobility, which they have sometimes touched or even grasped, and which they are therefore convinced were not the result of imposture or illusion. Five witnesses state that they have been touched by some invisible agency on various parts of the body, and often where requested, when the hands of all present were visible. Thirteen witnesses declare that they have heard musical pieces well played upon instruments not manipulated by any ascertainable agency. Five witnesses state that they have seen red-hot coals applied to the hands or heads of several persons without producing pain or scorching; and three witnesses state that they have had the same test applied to themselves with the like immunity. Eight witnesses state that they have received detailed information through rappings, writings, or in other ways, the accuracy of which was unknown at the time to themselves or to any persons present, and which, on subsequent inquiry, was found to be correct. One witness declares that he has received a precise and detailed statement, which, nevertheless, proved to be entirely erroneous. Three witnesses state that they have been present when drawings, both in pencil and colors, were produced in so short a time, and under such conditions, as to render human agency impossible. Six witnesses declare that they have received information of future events, and that in some cases the hour and minute have been accurately foretold days and even weeks before. In addition to the above, evidence has been given of trance-speaking, of healing, of automatic writing, of the introduction of flowers and fruits into closed rooms, of voices in the air, of visions in crystals and glasses, and of the elongation of the human body."

One of the latest scientific investigators of Spiritualism is Mr. William Crookes, F.R.S., discoverer of the metal thallium, editor of the *Chemical News* and of the *Quarterly Journal of Science*. In the latter journal for Jan., 1874, is an article by him, entitled, "Notes of an Inquiry into the Phenomena called Spiritual, 1870-73." He attests phenomena similar to those affirmed by the dialectical society's committee and its witnesses, which came under his notice in his own house, in the light, and with only private friends present except the medium, at times appointed by himself, and under circumstances which, he says, absolutely precluded the employment of the very simplest instrumental aids.

In 1881 the chief English journals of spiritualism were *Light, Medium and Daybreak, Spiritualist, Spiritual Notes*, weekly or monthly. In the U. S., the earliest was the *Banner of Light*, founded in 1857. In 1881 it was stated that there was in Germany 1 spiritualist magazine; in Austria, 1; Holland, 1; France, 1; Belgium, 4; England, 7; Italy, 1; Spain, 5; U. S., 5; Argentine Republic, 2; Mexico, 2; Colombia, 2. The literature of the movement is very voluminous. The following, in addition to those already indicated, are the principal works on spiritualism published in England and the U. S., to which we must refer our readers for further information: *From Matter to Spirit*, by Mrs. De Morgan, with preface by Prof. De Morgan; *The Two Worlds*, by Thomas Brevior; *Footfalls on the Boundary of Another World and The Debatable Land*, by Robert Dale Owen; *History of the Supernatural*, by William Howitt; *A Defense of Spiritualism*, by Alfred Russell Wallace; *Lights and Shadows of Spiritualism*, by D. D. Home (1877); *Mesmerism, Spiritualism, etc., Historically and Scientifically Considered*, by W. B. Carpenter, F.R.S. (1877); *Transcendental Physics* (Zöllner), *Psychic Facts*, by Harrison (1880); *The Identity of Primitive Christianity and Modern Spiritualism* (2 vols.), by Eugene Crowell, M.D.

SPIROMETER, the name of an instrument devised for the purpose of measuring the vital capacity of the lungs, or for gauging the amount of air that an individual can expire after a forced inspiration.

SPIRULA, a genus of polythamous, decapodous, dibranchiate cephalopods, comprising three species, and constituting Prof. Owen's family, *spirulidae*, in which the internal skeleton is in the form of a nacreous, discoidal shell, the whorls of which are not in contact with one another, and which are divided into a series of chambers by partitions pierced by a ventral tube or *siphuncle*. The animal has minute lateral fins, and there are six rows of small suckers on the arms (see CEPHALOPODA). The three species constituting the family, or the genus, which in this case is the same, are, as designated by Prof. Owen, *spirula*, *peronii*, *S. australis*, and *S. reticulata*, and are formed from the *nautilus spirula* of Linnæus. The shell of one or other of these species is not unfrequently found on the coasts of Ireland, Cornwall, and Devon. It is commonly known as the *post-horn*, and is similar in structure to that of the nautilus, but is lodged in the posterior part of the animal, and is therefore internal, whereas the shell of the nautilus is external. It corresponds to the phragmacone of the belemnite (q.v.). The shells are found in great numbers in certain localities, but the animal has seldom been taken whole. In its internal anatomy it is a true dibranchiate, having two branchiæ and an ink-bag. It has the peculiar feature that the hinder end of the body acts as a suctorial disk for fastening itself to foreign bodies. The beaks are not calcified, and the retractor muscles of the funnel spring from the inner surface of the last chamber of the shell, as in the nautilus. This chamber also lodges the hinder termination of the liver (Owen).

SPITALFIELDS, a district of London, adjoining Bethnal Green, derives its name from the *hospital* of St. Mary, founded there, in 1197, by Walter Brune and his wife Rosia, and is inhabited chiefly by silk-weavers and other poor people. The manufacture of silk was established in Spitalfields by emigrants from France, after the revocation of the edict of Nantes.

SPITHEAD, a celebrated roadstead off Portsmouth, England, and a favorite rendezvous of the British navy, is the eastern division—the Solent (q.v.) being the western division—of that strait which separates the isle of Wight from the mainland. It receives its name from the "Spit," a sand-bank stretching s. from the English shore for 3 m., and it is 14 m. long by about 4 m. in average breadth.

SPITZ DOG, a variety of the Pomeranian dog. It is small, with a bushy curved tail, sharp muzzle, short, ovate ears, long hair of a color ranging from white to cream, and sometimes jet black. It is thought to be a cross between the arctic fox and some of the small wolf-like arctic dogs. Of late it is somewhat in disfavor, as being snappish and liable to hydrophobia; though for this the proof seems not to be supplied.

SPITZBERGEN, a group of islands in the Arctic ocean, in lat. 76° 30'—80° 40' n., and long. 10°—32° e., lies 300 m. n. of Scandinavia, and 325 e. of Greenland. The group, which is estimated to contain about 30,000 English sq. m., is composed of three large and several small islands. The largest of the group, *Spitzbergen Proper*, consists of two oblong and parallel tracts known as West Spitzbergen and East Spitzbergen or New Friesland, connected by a neck of land; the whole strongly resembling a boat hook in shape. The two next in size are *Egede* and *North-east Island*. Being far within the Arctic circle, and surrounded by a wide expanse of sea, almost the whole of its surface is covered with perpetual snow and glaciers; yet the climate is considerably milder than on the North American coast much further south—a condition due to the gulf stream. The temperature depends rather upon the winds than the season, the coldest months being February, March, and April; the mean annual temperature is about 16° below freezing, and even in July and August is seldom more than 5° above the freezing point; yet, during this short summer, more than 100 species of plants, which constitute the vegetation of this inhospitable region, succeed in springing up, and producing and ripening their seed. The whole of Spitzbergen could not afford sustenance for one human being; but it is, nevertheless, a haunt of reindeer, foxes, and bears, and whales and seals

abound on the coast. Its mountains contain granite, marble, and coal. Spitzbergen has from time to time been occupied by Dutch and Russian colonies. It was discovered in 1596, by William Barentz, the Dutch explorer, in his third voyage to discover the North-east passage, and has since been frequently visited by other explorers, and by whalers. In the summer of 1897, Andree made Spitzbergen his starting-point in an attempt to reach the north pole by balloon. See *illus.*, GLACIERS, vol. VI.

SPLAY, the sloping or beveled opening in window recesses and other such openings. Also the corner taken off the outer angle of such openings.

SPLEEN, THE, is the largest and most important of the so called ductless glands, whose chief object is supposed to be to restore to the circulation any substances that may have been withdrawn from it. It is of an oblong flattened form, soft, of very brittle consistence, highly vascular, of a dark bluish-red color, and situated on the left hypochondriac region, with its interior slightly concave surface embracing the cardiac end of the stomach and the tail of the pancreas. (See GLANDS; PANCREAS; STOMACH.) It is invested by an external or serous coat, derived from the peritoneum, and an internal fibrous elastic coat. Mr. Gray, who wrote the Astley-Cooper prize essay, *On the Structure and Use of the Spleen*, states that the size and weight of this organ are liable to very extreme variations at different periods of life, in different individuals, and in the same individual under different conditions. In the *adult*, in whom it attains its greatest size, it is usually about 5 in. in length, 3 or 4 in breadth, and an inch or an inch and a half in thickness, and weighs about 7 ounces. At *birth* its weight in proportion to that of the entire body is as 1 to 350, which is nearly the same ratio as in the adult; while in *old age* the organ decreases in weight, the ratio being as 1 to 700. The size of the spleen is increased during and after digestion, and is large in highly fed, and small in starved animals. In intermittent fevers and leucocythemia it is much enlarged, weighing occasionally from 18 to 20 lbs., and constituting what is popularly known as the *ague-cake*.

On cutting into the spleen a section of it shows the presence of numerous small fibrous bands termed *trabeculae*, united at numerous points with one another, and running in all directions. The parenchyma, or proper substance of the spleen, occupies the interspaces of the above described areolar framework, and is a soft pulpy mass of a dark reddish-brown color, consisting of colorless and colored elements. The *colorless elements* are described by Gray as consisting of granular matter, of nuclei about the size of the red blood-disks, and a few nucleated vesicles; and as constituting one-half or two-thirds of the whole substance of the pulp in well-nourished animals, while they diminish in number, and sometimes altogether disappear in starved animals. The *colored elements* consist of red blood-disks and of colored corpuscles either free or included in cells; sometimes enlarged blood-disks are seen included in a cell, but more frequently the enclosed disks are altered in form and color, as if undergoing retrograde metamorphoses. Besides these, numerous deep-red, or reddish-yellow, or black corpuscles and crystals, closely allied to the hæmatin of the blood, are seen diffused through the pulp substance.

The venous blood of the spleen is carried away by the splenic vein, which contributes to form the great portal venous system, distributed through the liver; while arterial blood is supplied by the splenic artery, the largest branch of the celiac axis. The branches of this artery subdivide and ramify like the branches of a tree, with the *malpighian* or *splenic corpuscles* attached to them like fruit. These splenic corpuscles, originally discovered by Malpighi, are whitish spherical bodies, which are either connected with the smaller arterial branches by short pedicles, or are sessile upon their sheaths. They vary considerably in size and number, their diameter usually ranging from one-third to one-sixth of a line. Each consists of a membranous capsule, homogeneous in structure, and formed by a prolongation from the sheath of the artery. The blood-vessels ramifying on the surface of a corpuscle consist of the larger branches of the artery with which it is connected, of venous branches, and of a delicate capillary plexus. From this arrangement of the vessels, it may be inferred that active changes are carried on in the contents of these corpuscles, which consist of a soft, white, semi-fluid substance, made up of granular matter, nuclei similar to those found in the pulp, and a few nucleated cells. These splenic corpuscles are much more distinct in early life than subsequently, and are much smaller in man than in most mammals. They, however, bear a remarkable relation to the general state of nutrition, being much the greatest in well-fed animals, especially in the early periods of the digestion of albuminous food; while they diminish extremely in ill-fed animals, and in those that have been starved, they disappear altogether.

The chemical composition of the spleen confirms the view that a retrograde change of tissue occurs very freely in it. In 1000 parts there were found (by Oidtmann) nearly 250 of solid residue, of which more than 243 were organic, consisting of albumen, fats, inosite, uric acid, sarcine, xanthine, leucine, tyrosine, and pigment, all of which, excepting the first two, are products of the metamorphosis of tissue. This gland also contains a large quantity of oxide of iron, obtained probably from the disintegration of red blood-disks in it.

With regard to its uses, it may be regarded as a storehouse of nutritive material, which may be drawn upon according to the requirements of the system; and of the

exertion of an assimilative action upon the albuminous matter, during its withdrawal from the general current of the circulation, we have direct evidence in the large increase in the proportion of fibrine contained in its venous blood—the blood of the splenic vein sometimes containing nearly six times the usual quantity of fibrine. Before the institution of the chemical inquiries which led to the above conclusion, it was held that the function of the organ was to act as a reservoir for the portal blood, with the view of preventing the portal vessels from being unduly distended during the digestive process. To what extent it is the seat of the disintegration of old blood-corpuscles, and of the formation of new ones, is still uncertain. The removal of this organ from the body has frequently been performed in animals without serious effects; but in some of these cases, small secondary spleens are developed, and in others, various sets of lymphatic glands are observed to increase rapidly, shortly after the operation, and these probably act vicariously for the spleen. Its singular and complicated microscopic structure, and its extreme vascularity, would lead to the inference that this is a highly important viscus.

It is unnecessary to enter into any detail regarding the diseases of the spleen, as most of them occur secondarily in the course of other affections, as in intermittent fever (ague) and leucocythemia (q.v.), when it is sometimes enlarged to 40 times its natural weight. It is sometimes diminished to the size of a walnut, the cause of this atrophy being unknown, but the apparent result being a loss of color, and a comparatively bloodless condition. The spleen is also liable to the singular morbid change known as *waxy degeneration*, in which the presence of starch like amyloid granules is observed in the tissue on submitting it to microscopico-chemical investigation. These remarkable granules dissolve when heated in water, and by the action of iodine acquire a bluish tint, but not the pure iodide of starch purple. In their ultimate composition, however, these granules resemble the albuminates rather than starch, inasmuch as they contain nitrogen.

SPLEEN WORT. See ASPLENIUM.

SPLENIC APOPLEXY, a disease of cattle and sheep, resembles black quarter (q.v.) in suddenly attacking animals in good thriving condition, and, like it, appears to depend upon the rapid manufacture of insufficiently elaborated blood, probably faulty in the healthy proportion of some of its constituents. The animal staggers, froths at mouth, throws itself about in convulsions, and sometimes dies within an hour. Few cases recover. The blood is thin, dark-colored, and indisposed to coagulate. It accumulates in the large internal organs, particularly in the liver and spleen, and is poured out on the mucous surfaces. If the animal is seen in time, and before the pulse becomes small and weak, a moderate bleeding may be tried. A full dose of physic, with a prompt stimulant, must at once be given, and cloths wrung out of hot water applied, for several hours continuously, to the belly and loins. If the animal is weak, and the pulse scarcely perceptible, stimulants must be freely given from the first; and where there is stupor, cold water likewise applied to the head. To prevent the disease, attention must be paid to regular moderate feeding; abundance of wholesome water must be supplied; the grazings not allowed to become too rank, and changed occasionally; rock-salt placed within reach; and a seton inserted in the dewlap of all cattle and sheep pastured upon lands subject to splenic apoplexy. See PASTEUR: GERM THEORY.

SPLENIZATION is a term employed in morbid anatomy to indicate a diseased condition of the lung, in which the tissue of that organ resembles that of the spleen in various physical points, such as softness, friability, etc.

SPLINT, or **SPLENT**, is a bony enlargement on the horse's leg, between the knee and fetlock, usually appearing on the inside of one or both fore-legs, frequently situated between the large and small canon bones, depending upon concussion, and most common in young horses that have been rattled rapidly along hard roads before their bones are consolidated. When of recent and rapid growth, the splint is hot and tender, and causes lameness, especially noticeable when the horse is trotted along a hard road. A piece of spongiopiline saturated with cold water should be applied to the splint, kept in position with a light linen bandage, and wetted with cold water or a refrigerant mixture every hour. Perfect rest must be enjoined for ten days or a fortnight. When the limb is cool, and free from tenderness, the swelling, which will still remain, may be greatly reduced by some stimulating applications, such as the ointment of the red iodide of mercury, the common fly blister, or the firing iron.

SPLINT-BONES. The horse and certain allied mammals have what is popularly known as an outer and an inner splint-bone in the skeleton of the leg. Beyond the bones of the carpus and tarsus, there is one very large bone (the metacarpal or metatarsus of the third toe), which supports the whole weight of the animal. On either side of this bone are the outer and inner splint-bones, which are small bones, not running more than half the length of the great central bone, into which they merge. They represent, in a rudimentary form, the metacarpal and metatarsal bones of the fourth and second toe.

SPLINTS, in surgery, are certain mechanical contrivances for keeping a fractured limb in its proper position, and for preventing any motion of the fractured ends: they are also employed for securing perfect immobility of the parts to which they are applied in other cases, as in diseased joints, after resection of joints, etc.

Ordinary splints are composed of wood carved to the shape of the limb, and padded; the best pads being made out of old blankets, which should be cut into strips long and wide enough to line the splints, and laid in sufficient number upon one another to give the requisite softness. The splints should be firmly bound to the previously bandaged limb with pieces of bandage, or with straps and buckles; care being taken that they are put on sufficiently tight to keep the parts immovable, and to prevent muscular spasm, but not so tight as to induce discomfort. Gutta percha, sole-leather, or pasteboard, after having been softened in boiling water, may in some cases advantageously take the place of wooden splints. They must be applied when soft to the part they are intended to support, so as to take a perfect mold, and then be dried, stiffened, and, if necessary, lined. An account of the more complicated kinds of splint required in certain cases, as Macintyre's splint, Liston's splint, etc., may be seen in any illustrated catalogue of surgical instruments.

The ordinary splint is now to a great degree superseded by immovable bandages, which consist of the ordinary bandage saturated with a thick mucilage of starch, or with a strong solution of a mixture of powdered gum-arabic and precipitated chalk, which, when dry, form a remarkably light but firm support. As, however, these bandages require some hours to dry and become rigid, means must be used to counteract any displacement of the limb in the interval. On this account, many surgeons prefer the plaster of Paris or gypsum bandage, which is applied in the following manner: the limb being protected by a layer of cotton-wool, a bandage composed of coarse and open material, into which as much dry powdered gypsum as possible has been rubbed, must be immersed in water for about a minute, and then rolled around the limb in a spiral manner, just as an ordinary bandage; after every second or third turn of the bandage, the left hand of the surgeon should be plunged into water, and smeared over the part last applied. When the whole has been thus treated, the exterior of the bandage should be smeared over with a paste of gypsum and water until a smooth surface and complete rigidity have been attained—a process not occupying more than 10 minutes or a quarter of an hour. In a case of simple fracture, where no surgical aid is at hand, any non-professional person of ordinary intelligence might apply this bandage, extreme care being taken that the ends of the broken bone are in their proper position.

SPLÜGEN, a mountain of the Lepontine Alps, in the Grisons, Switzerland, whose summit, 10,748 ft. high, bears the name of the Tambohorn. The pass of the Splügen, connecting the s.e. of Switzerland with the region of Italy round lake Como, is at its highest point 6940 ft. above the sea, and in its present condition is the work of the Austrian government (1821). The southern or Italian descent has three great "galleries"—i. e., covered portions of the pass constructed of solid masonry, and intended to protect the road from avalanches. They are the longest on any Alpine high-road. When Marshal Macdonald conducted the French army of reserve across the Splügen by the old path, Nov. 27-Dec. 4, 1800, he lost severely in men and horses from the fall of avalanches.

SPOFFORD, AINSWORTH R., b. N. H., 1825; was educated privately, chiefly as a classical scholar; was made an assistant librarian in the library of congress, and in 1865 became principal librarian. He had already published (1864) the *Alphabetical Catalogue of the Library of Congress*, and this was followed by supplements, the series being valuable aids to general bibliography. The library of congress, which contained 90,000 volumes in 1865, had grown in 1880 to more than 300,000, and Mr. Spofford's influence was used with successive congresses to obtain an appropriation for a building suitable for so large and increasing a collection. In this he was measurably successful, and a commodious and appropriate structure will probably be erected. Mr. Spofford is recognized as a bibliographer of erudition and remarkable natural gifts, adapting him for the responsible position of librarian in the national library. Besides his work in cataloguing, he has published the *American Almanac*, 1878-91; a comprehensive storehouse of chronology and facts in finance and politics.

SPOFFORD, HARRIET ELIZABETH (PRESCOTT), b. Me., 1835; received her education at Newburyport, Mass., and in 1865 married Richard S. Spofford, a lawyer of Boston. She has been a frequent contributor to the *Atlantic Monthly*, *Harper's Monthly*, and other periodicals. She wrote *Str Rohan's Ghost* (1859); *The Amber Gods, and Other Stories* (1863); *Azarian, an Episode* (1864); *New England Legends* (1871); and *The Thief in the Night* (1872); *Scarlet Poppy and Other Stories* (1894); *A Master Spirit* (1896).

SPOHR, LUDWIG, an eminent German musical composer and violinist, son of a physician of Brunswick, was b. in that town in 1784. He began his violin studies in boyhood; at the age of 12 he played a violin concerto of his own at the court of Brunswick; and at 13 he obtained an appointment as chamber-musician to the duke. A few years later he made a musical tour through Russia and Germany, giving concerts, and acquiring a high reputation as a performer on the violin. In 1805 he became music director at the court of Saxe-Gotha, and held afterward for several years the office of music director of the Theater an der Wien at Vienna. He visited Italy in 1817. Paris in 1819, and in 1820 appeared in London, where he was received with great applause at the Philharmonic society's concerts, and produced two symphonies and an overture. In 1822 he became kapellmeister at the court of Hesse-Cassel, which post he continued to

hold till 1857, when he retired from professional life. He died in 1859. Spohr's musical works include seven operas—*Faust*, *Jessonda*, *Zemira und Azor*, *Der Zweikampf der Geliebten*, *Der Berggeist*, *Peter von Albano*, and *Der Alchymist*; three oratorios, *Die letzten Dinge*, *Des Heiland's letzte Stunden* (Calvary), and *Der Fall Babylons*; various masses, psalms, and hymns, six grand symphonies, four overtures, besides nonets, quartets, violin concertos, sonatas for violin and harp, fantasias, and rondos. *Die letzten Dinge*, or Last Judgment, is a very grand and very attractive work; so also is *Der Fall Babylons*, first produced at a Norwich musical festival. Of his operas the most esteemed are *Faust* and *Jessonda*, the latter remarkable for its successful embodiment of the spirit of oriental poetry. His songs are rather deficient in broad and decided melody; but his instrumental works occupy a very high place in the estimation of musicians, more especially the C minor symphony, and the symphony known as *Die Weihe der Töne*. His *Violinschule* is a complete work on violin playing.

SPOKANE, a co. in n.e. Washington, formed 1879, from part of Stevens co.; 1680 sq. m.; pop. '90, 37,487. Co. seat, Spokane.

SPOKANE, city and co. seat of Spokane co., Wash.; on the Spokane river and the Great Northern, the Northern Pacific, the Oregon Railroad and Navigation Co.'s line, and the Spokane Falls and Northern railroads. It is at the cascades of the river, which here has a fall of over 150 feet, and furnishes power for manufacturing and for electric railroads, as well as the water supply of the city. The city is the seat of a Protestant Episcopal bishopric, and of fort Spokane, a U. S. military post. It has a city hall, co. court house, Gonzaga college (R. C.), academy of the Holy Names (R. C.), St. Mary's hall (P. E.), public library, Sacred Heart hospital, St. Joseph's orphanage, deaconess home, home of the friendless, 12 bridges, including a cantilever 1500 ft. long, electric lights, national and private banks, over 60 churches, and daily, weekly, and monthly periodicals. The principal industries are mining, milling, lumbering, manufacturing, and farming. Pop. '90, 19,992.

SPOLETO (Latin, *Spolegium*), a city of central Italy, province of Perugia, is situated on a rocky hill, 61 m. n.n.e. of Rome. Pop. '81, 7696. It is commanded by a citadel, *La Rocca* (now a prison), which in 1499 was inhabited by Lucretia Borgia. The streets are steep, narrow, and dirty. The town is united with the neighboring height of *Monte Luco* by an imposing bridge and aqueduct, 290 ft. in height, dating from Roman times, but restored in 14th c. Spoleto has a fine cathedral, built in the time of the Lombard dukes, and several interesting churches and palaces.

SPONGE, *Spongia*, a genus which originally included all the numerous genera and species of the family *spongiade*, all of which are still commonly spoken of by naturalists as sponges, although in its more popular sense that term is limited to a few kinds, or to their fibrous framework. The sponges are creatures of very low organization, concerning which there has been much difference of opinion, whether they ought to be referred to the animal or to the vegetable kingdom. At first referred to the *Protozoa*, and later to the *Calenterata* (see ZOOLOGY), they are now considered by the greater number of naturalists as entitled to rank as a separate sub-kingdom, *Porifera*, characterized by the multitude of mouths or inhalent apertures which open through the body wall, the primitive mouth of the two-layered sac-like embryo being converted into the large exhalent opening. They may be classified as follows: 1. *Myxospongiae*, destitute of skeleton; 2. *Fibro-spongiae*, having a fibrous skeleton, with or without siliceous spicules; 3. *Calcspongiae*, having calcareous spicules. These spicules are not purely natural or mineral, but contain a trace of organic or animal matter, by the growth of which their form is determined upon. They are most beautiful microscopic objects, and spicules of different forms are sometimes found in the same species, sometimes lying close together in bundles, sometimes straight or slightly curved, sometimes in the shape of needles pointed at one end, or at both; sometimes of needles radiating from a center; while some have a head at one end like a pin, some have grapnel-like hooks at the ends. Some of the species with horny framework have spicules imbedded in it; some have them implanted in the fibers; some are destitute of them. There is a beautiful West Indian species, *dictyocalyx pumiceus*, in which the siliceous matter becomes itself a fibrous network, and is so fine and transparent as to resemble spun glass. In a living state many sponges exhibit lively colors, from the presence of some coloring matter, or from iridescence. Like the higher animals, the body of the sponge is composed of a distinct outer layer of cells, the ectoderm or epidermis, and a ciliated inner layer or endoderm (often restricted to definite areas, the so-called ciliated chambers), between which a middle layer of cells, the mesoderm, arises. This may be of very variable thickness, and gives rise to the skeleton. From the close resemblance which the cells of the ectoderm and mesoderm present to *Amoeba*, and those of the endoderm to those infusoria known as *Monads*, it has been argued that the sponge is a mere colony of *Protozoa*. But its development accords too closely with that of higher animals to admit of such a view, a free-swimming ciliated larva being produced by segmentation of a fertilized ovum. In the sponge, however, we have a degree of independence of the cell units far greater than that which exists in any other group—a divided sponge readily reunites and adjacent masses grow together. They assume very various forms, which are characteristic of the different genera and species. Some are nearly globular; some cup-shaped, top-shaped, conical, cylindrical, thread-like, etc.; some are simple, and some branched.

The surface of a living sponge is generally covered with minute pores, through which

water is imbibed, carrying with it both the air and the organic particles necessary for the support of life. The pores are supposed to be permanent in many of the sponges, and the currents which enter through them to be produced by cilia, although these have as yet been detected only in a few species. But in those of the very lowest organization the pores seem to be formed for the occasion, just as the *amœba* opens anywhere to admit food within its substance. In *spongilla fluviatilis*, a small fresh-water species found in Britain, the opening and closing of each pore occupies less than a minute, and the pores do not open simultaneously, but in irregular succession, and apparently never again in precisely the same spot. No trace of the pore remains for an instant after its closing, nor is there any indication of the point where a new one is to open. The water which enters by the pores passes out of some sponges by a single orifice, which serves for the whole mass; others have numerous orifices (*oscula*) which are permanent, and are much larger than the pores by which the water is imbibed, the whole mass being pervaded by canals which lead from the pores to these orifices, from which, under the microscope, a constant discharge of water may be seen taking place, minute opaque particles being carried along with its current. These particles are not only fecal matter, but gemmules and ova.

Reproduction takes place both by gemmation and by true ova. Many of the gemmules go on to increase the sponge-mass; but the greater part finally become detached, and are carried out into the water to settle down in a new locality. Mr. Huxley has detected true ova and sperm-cells imbedded in the substance of sponges.

The sponges employed for domestic and other purposes derive their value from the elasticity and compressibility of their fibrous framework, divested of the gairy substance, and its power of imbibing fluids. The absence of spicules is essential to a useful sponge. The kinds fit for use are found in the seas of warm climates. Some small species of sponge live at great depths. One has been brought up in the gulf of Macri from a depth of 185 fathoms. Numerous species of sponge are very abundant on many parts of the British coasts.

Fossil remains of sponges are found in many rocks, and of horny, fibrous kinds, as well as of those with calcareous or siliceous framework.

Several species of sponge are in use for economical purposes. Two species are chiefly brought from the Levant, and a very inferior one from the West Indies and coast of Florida. The trade in sponge is very considerable; is carried on chiefly by the Turks and the inhabitants of the Bahama islands. The number of men employed in the Ottoman sponge-fishery is between 4,000 and 5,000, forming the crews of about 600 boats. These boats find their chief employment on the coast of Candia, Barbary, and Syria. The sponge is obtained by diving, the diver taking down with him a flat piece of stone of a triangular shape, with a hole drilled through one of its corners; to this a cord from the boat is attached, and the diver makes it serve to guide him to particular spots. When he reaches the growing sponges, he tears them off the rocks, and places them under his arms; he then pulls at the rope, which gives the signal to his companions in the boat to haul him up. The value of sponges collected in Greece and Turkey is from \$450,000 to \$500,000 annually. The Greeks of the Morea, instead of diving, obtain sponges by a pronged instrument; but the sponges thus collected are torn, and sell at a low price. The best sponges are obtained on detached heads of rock in 8 or 10 fathoms of water.

The sponges of the Bahamas and other West Indian islands are of a larger size and coarser quality; but large quantities are gathered; and about 215,000 lbs., worth £17,000, are sent annually to Great Britain. The sponges are torn from the rocks by a fork at the end of a long pole. To get quit of the animal matter they are buried for some days in the sand and then soaked and washed.

The domestic uses of sponge are familiar to every one. It is also of great value to the surgeon, not only for removing blood in operations, but for checking hemorrhage. Burnt sponge was once a valid remedy for scrofulous diseases and goiter; but iodine and bromine, from which it derives all its value, are now administered in other forms.

SPONSOR (Lat. one who promises), the name given in theological use to a godfather or godmother (q. v.). The name is derived from the circumstance, that in baptism or confirmation, and especially in infant baptism, the sponsor is understood to make certain promises or engagements in the name and on the part of the person baptized or confirmed. The idea of sponsorship is entirely rejected not only by Baptists, but generally also by Presbyterians and Independents.

SPONTANEITY, the name for the doctrine, referring to the human mind, that muscular action may, and does, arise from purely internal causes, and independent of the stimulus of sensations. It had long been the tacit assumption in mental philosophy, that we are never moved to action of any kind, except under the stimulation of some feeling, some pleasure or pain, or some end in view. To this is now opposed the doctrine of the spontaneous commencement of movements under certain circumstances; which, however, does not exclude, but only supplements, the operation of the feelings in stimulating movements, as in the ordinary course of voluntary action. The doctrine supposes that the nerve-centers, after repose and nourishment, acquire a fullness of vital energy, which discharges itself in the play of movement, without any other occasion or

motive; the addition of a feeling, or end, enhances and directs the activity, but does not wholly create it.

Of the various proofs and illustrations of spontaneity, perhaps the most striking is that furnished by the movements of young animals of the active species. A young dog or kitten shows a degree of activity out of all proportion to any feeling to be gratified, or any end to be served; we can interpret it only as internal energy seeking vent, irrespective of the pursuit of pleasure or the avoidance of pain—in other words, the action of the will. When the accumulated energy is expended, the animal falls back into a state of repose, and is then roused only by the stimulus of sensation. The state called “freshness” in a horse, for example, is a state of superabundant and irrepressible activity. Children go through the same phase: after rest or confinement, they burst forth incontinently into some form of active excitement, of which a part may be considered as pure spontaneity, while part may be owing to sensation.

The doctrine is well fitted to express the difference between the active and the sensitive temperaments: for if it were true that actions is in proportion to the stimulation of the feelings, the most susceptible characters would be the most active. But, in point of fact, the active temperament is manifested by a profusion of activity for its own sake, with little circumspection or regard to consequences; and constitutes the restless, bustling, roughshod, energetic, and enterprising disposition of mind, as seen in sportsmen, soldiers, travelers, etc.

The explanation of the growth of the will (q.v.), or voluntary power, involves the spontaneous beginning of movements.—See Bain on *The Senses and the Intellect*, 2d edit., p. 76.

SPONTANEOUS COMBUSTION is a phenomenon that occasionally manifests itself in mineral and organic substances. The facts connected with the spontaneous ignition of mineral substances are well known to chemists, and some of them have been already described in the article *Pyrophorus* (q.v.). Ordinary charcoal does not undergo combustion in air under a temperature of 1000°, but in some states it is liable spontaneously to acquire a temperature which may lead to unexpected combustion. Thus, lamp-black impregnated with oils, which contain a large proportion of hydrogen, gradually becomes warm, and inflames spontaneously. According to M. Aubert, Chevallier, and other French observers, recently-made charcoal, in a state of fine division, is liable to be spontaneously ignited without the agency of oil; but we are not aware that this phenomenon has been observed in this country. There have been many instances of the spontaneous ignition of coals containing iron pyrites (q.v.) when moistened with water. The pyrites which most readily give rise to spontaneous combustion are those in which the protosulphide is associated with the bisulphide of iron; and these occur in the Yorkshire coals from Hull, and in some kinds of South Wales coal. Sulphur has no tendency to spontaneous combustion, but Dr. Taylor refers to an instance that came to his own knowledge, in which there was reason to believe that the vapor of bisulphide of carbon in an india-rubber factory was ignited by solar heat traversing glass. Phosphorus, when in a dry state, has a great tendency to ignite spontaneously, and it has been observed to melt and take fire (when touched) in a room in which the temperature was under 70°. The ordinary lucifer-match composition is luminous in the dark, in warm summer nights, which shows that oxidation, and therefore a process of heating, is going on. Hence, large quantities of these matches kept in contact may produce a heat sufficient for their ignition. “I have seen them ignite,” says Dr. Taylor, “as a result of exposure to the sun’s rays for the purpose of drying.”—*Principles and Practice of Medical Jurisprudence*, 1865, p. 603.

From these cases occurring in the mineral kingdom, we pass to the consideration of spontaneous combustion in organic substances. Passing over the accidents that may result from the admixture of strong nitric or sulphuric acid with wool, straw, or certain essential oils, and which, if they occur, are immediate and obvious, we have to consider the cases in which, “without contact with any energetical chemical compounds, certain substances—such as hay, cotton, and woody fiber generally, including tow, flax, hemp, jute, rags, leaves, spent tan, cocoa-nut fiber, straw in manure-heaps, etc.—when stacked in large quantities in a damp state, undergo a process of heating from simple oxidation (eremacausis) or fermentation, and, after a time, may pass into a state of spontaneous combustion.”—Taylor, *op. cit.*, p. 606. There is undoubted evidence that hay and cotton in a damp state will occasionally take fire without any external source of ignition. Cotton impregnated with oil, when collected in large quantity, is especially liable to ignite spontaneously; and the accumulation of cotton-waste, used in wiping lamps and the oiled surfaces of machinery, has more than once given rise to accidents, and led to unfounded charges of incendiarism. Dr. Taylor relates a case in which a fire took place in a shop “by reason of a quantity of oil having been spilled on dry sawdust.” According to Chevallier, vegetables boiled in oil furnish a residue which is liable to spontaneous ignition; and the same chemist observes that all kinds of woollen articles imbued with oil, and collected in a heap, and hemp, tow, and flax, when similarly treated, may ignite spontaneously. In the case of *Hepburn v. Lordan*, which came before vice-chancellor Wood in Jan., 1865, and was carried by appeal before the lords justices in the following month, an attempt was made to prove that wet jute was liable to undergo spontaneous

combustion: and the great fire at London Bridge in 1861 was referred to the spontaneous combustion of jute in its ordinary state. With regard to the latter hypothesis, Dr. Taylor remarks that it is wholly incredible, and from experiments which he made for the defendants in the above lawsuit, and on other grounds, he holds that there is no evidence of moist jute undergoing spontaneous combustion; but, he adds, although no cases are recorded, it is probable that jute, cocoa-nut fiber, and linen and cotton rags, imbued with oil, might undergo this change. Dry wood is supposed by Chevallier and some other chemists to have the property of igniting spontaneously. Deal which has been dried by contact or contiguity with flues or pipes conveying hot water or steam at 212° , is supposed to be in a condition for bursting into flame when air gets access to it; and the destruction of the houses of parliament, and many other great fires, have been ascribed to this cause; but from the experience of Dr. Taylor (*op. cit.*, p. 615) this view must be regarded as untenable.

It is still an open question whether such organic nitrogenous matters as damp grain or seeds of any kind ever undergo spontaneous combustion. In a case recorded in the *Annales d'Hygiène* for 1841, MM. Chevallier, Ollivier, and Devergie drew the conclusion that a barn had caught fire from the spontaneous combustion of damp oats which were stored in it. No such cases are known to have occurred in this country.

The subject of the article is of extreme importance, not only because it may cause great destruction of life and property, but because it may lead to unjust charges of incendiarism.—For further details regarding it the reader is referred to Graham's "Report on the Cause of the Fire in the Amazon," in the *Quarterly Journal of the Chemical Society*, vol. v. p. 34; to the article "Combustion" in *Watts's Dictionary of Chemistry*, vol. i.; and to the elaborate chapter on this subject in Taylor's *Principles and Practice of Medical Jurisprudence*.

SPONTANEOUS COMBUSTION OF THE HUMAN BODY. In medico-legal works, cases are recorded, generally of a somewhat ancient date, in which it was supposed that the body was either spontaneously consumed by inward combustion, or acquired such extraordinary combustible properties as to be consumed when brought into contact with fire. The following is the first of one of the cases on record. It rests on the authority of Le Cat, a distinguished surgeon of his time, and is stated to have occurred at Rheims in 1725. The remains of a woman named Millet were found burned in her kitchen, about eighteen inches from the open fireplace. Nothing was left of the body except some parts of the head, of the legs, and of the vertebræ. Suspicion was excited against the husband, and a criminal inquiry was instituted; but learned experts reported that the case was one of spontaneous combustion, and the prisoner was acquitted. The facts are explicable on the supposition that the clothes of the deceased woman were accidentally ignited; and although the almost complete destruction of the body appeared to the medical men of that time to be inconsistent with the ordinary effects of fire, subsequent observations have shown that this is an error. In reference to this case, Liebig observes that it is easy to see that the idea of spontaneous combustion arose at a time when men entertained entirely false views on the subject of combustion, its essence, and its cause. What takes place in combustion generally has only been known since the time of Lavoisier (about a century ago), and the conditions which must be combined in order that a body should continue to burn, have only been known since the time of Davy, or for little more than half a century. From the time when the case of Millet occurred to the present day, probably somewhat over 50 supposed cases have been recorded. (In an article published on the subject by Dr. Frank of Berlin in 1843, 45 cases are adduced.) From an analysis of all the cases on record up to 1851, Liebig arrives at the conclusion that the great majority agree in the following points. "1. They took place in winter. 2. The victims were brandy-drinkers in a state of intoxication. 3. They happened where the rooms are heated by fires in open fireplaces and by pans of glowing charcoal, in England, France, and Italy. In Germany and Russia, where rooms are heated by means of closed stoves, cases of death ascribed to spontaneous combustion are exceedingly rare. 4. It is admitted that no one has ever been present during the combustion. 5. None of the physicians who collected the cases, or attempted to explain them, has ever observed the process, or ascertained what preceded the combustion. 6. It is also unknown how much time had elapsed from the commencement of the combustion to the moment when the consumed body was found."—*Letters on Chemistry*, 3d ed. 1851, p. 282. Out of the 45 cases collected by Frank, there are only three in regard to which it is assumed that combustion took place when no fire was in the neighborhood; and Liebig distinctly shows that these three solitary cases are totally unworthy of belief. With regard to the other cases, the writers who record them do not deny the presence of fire, but assume that the body was ignited by the fire, and then burned on like a candle or a bundle of straw, under similar conditions, till nothing but ashes or charcoal was left. These writers maintain that excess of fat, and the presence of brandy in the body, induce an abnormal condition of easy combustibility; but Liebig shows, by numerous illustrations, the utter fallacy of this view; and adds, as further evidence, "the fact that hundreds of fat, well-fed brandy-drinkers do not burn when by accident or design they come too near a fire. It may with certainty be predicted that, so long as the circulation continues, their bodies would not take fire, even if they held a hand in the fire till it was charred."—Spontaneous combustion in a living body is (he

adds) absolutely impossible. Notwithstanding the wide promulgation of Liebig's views, the belief in the possible occurrence of spontaneous combustion seems not yet to have disappeared. In 1847 the body of a man, aged 71, and who was neither fat nor a drunkard, was found in bed in a state of combustion. Dr. Nasson, who was commissioned to investigate the case, reported that the burning must have resulted from some inherent cause in the person—probably roused into activity by a hot brick that was placed at his feet; and Orfila is reported to have coincided in this opinion. This case is reported in the *Gazette Médicale*, Sept. 4, 1847. On June 13, 1847, the countess of Goerlitz was found dead in her bedroom, with the upper part of her body partly consumed by fire. The head was a nearly shapeless black mass, with the charred tongue protruding from it. The physician who was consulted could suggest no other explanation than that the body of the countess must have taken fire spontaneously, and not even by ignition of her dress by a candle. On this evidence she was buried; but circumstances having led to the suspicion that she had been murdered by her valet Stauff (who had been detected in attempting to poison the count), her body was exhumed in Aug., 1848, fourteen months after her death, and was subjected to a special examination by the Hesse medical college, who reported that she had not died from spontaneous combustion. The case was then referred to Liebig and Bischoff, and their report was issued in Mar., 1850, when Stauff was put upon his trial. They found no difficulty in concluding that the body was wilfully burned *after death*, for the purpose of concealing the murder (either by strangulation or a blow on the head) which had been previously perpetrated. The prisoner was convicted, and subsequently confessed that he had committed the murder by strangulation, as indeed the protruded tongue might have suggested. Since that date there has not been any case of alleged spontaneous combustion.—On this subject the reader is referred to the various articles on "Spontaneous Combustion" in the medical dictionaries and encyclopædias; to Dupuytren's *Leçons Orales*; to Liebig's *Letters on Chemistry*; and to Taylor's *Medical Jurisprudence*.

SPONTANEOUS GENERATION. See GENERATION, SPONTANEOUS.

SPONTOON, a weapon bearing resemblance to a halberd, which, prior to 1787, was borne instead of a half-pike by officers of British infantry. It was a medium for signaling orders to the regiment. The spontoon planted in the ground commanded a halt; pointed backward or forward, advance or retreat; and so on.

SPOOL, in spinning, a wooden reel for winding yarn upon. In sewing and lace-making machines, the spools are of metal, and their forms vary according to the requirements of the machine.

SPOONBILL, *Platalea*, a genus of birds of the Heron family (*Ardeidae*), much resembling storks both in their structure and their habits, but distinguished by the remarkable form of the bill, which is long, flat, broad throughout its whole length, and much dilated in a spoon-like form at the tip. The species are not numerous, but are widely distributed. The only European species is the WHITE SPOONBILL (*P. leucorodia*), rare in Britain, although in former times, before the draining of the fens in England, it was a more frequent summer visitor. It is common in Holland, in marshy districts throughout the northern parts of Europe and Asia in summer, and in the salt marshes of the coast of Italy in winter. It also inhabits Africa, and its range extends over the whole of that continent. It is gregarious, and the flocks of spoonbills generally make their nests in woods, in the tops of lofty trees. It is considerably smaller than the common heron. Its color is white, slightly tinged with pink; the bill and legs are black. A curious convolution of the windpipe, in the form of the figure 8, is found on dissection in the adult spoonbill, but does not exist in the young. The flesh of the spoonbill is said to be tender and of good flavor. The spoonbill is easily tamed, is quiet and inoffensive, feeds readily on any offal.—The ROSEATE SPOONBILL (*P. ajaja*) is an American species; very abundant within the tropics, and found in the most southern parts of the United States. It is nearly equal in size to the white spoonbill, which it resembles in its habits. It is a beautiful bird, with plumage of a fine rose-color, of which the tint is deepest on the wings; the tail-coverts crimson.

SPO'RADES. See ARCHIPELAGO.

SPORADIC (Gr. scattered) is a term applied to any disease that is naturally epidemic or contagious, when it attacks only a few persons in a district, and does not spread in its ordinary manner. The conditions on which the occurrence of epidemic or contagious diseases in a sporadic form depend are unknown. Among the diseases which occur in this form may be especially mentioned catarrh, cholera, dysentery, measles, scarlatina, and small-pox.

SPORE, in botany, may be called the *seed* of a cryptogamous plant, as it serves the same purpose of reproduction as the seed of a phanerogamous or flowering plant, and after remaining for a time in a state of rest, is developed into a new plant on the occurrence of the necessary conditions. A spore, however, differs very much from the seed of a phanerogamous plant, as it always consists of a single cell, and therefore does not con-

tain any *embryo* or rudiment of the future plant. In its formation, it corresponds rather with the grains of pollen in the anther of a flower. Spores are small, often so minute as to be invisible to the naked eye—many of them extremely minute, so that they may be wafted about unperceived. This, indeed, might be expected from the very small size of many of the cryptogamic plants themselves, as moulds and many other fungi. But even the spores of the largest ferns are very small. Spores often remain capable of germination for many years, and they seem to be capable of enduring much drought without destruction. They seem to germinate indifferently from any part of their surface, in which they differ essentially from the seeds of phanerogamous plants. In the parent plant, they are either scattered singly, or are united in a fruit-like envelope, which is generally known as a *sporangium*, or *spore-case*. In some plants they are united in definite numbers, as of four (*tetraspore*), surrounded by an envelope (*perispore*, or *sporidium*). The peculiar reproductive organ, which in some cryptogamous plants produces the spores, is called a *sporocarp*, or a *sporophore*. In many plants, as in mushrooms, the production of spores belongs exclusively to a part of the plant called the *hymenium*. See *illus.*, LYCOPODIACEÆ, vol. IX.

SPORTS, BOOK OF, the name popularly given to a declaration issued by James I. of England in 1618, to signify his pleasure that on Sundays, after divine service, "no lawful recreation should be barred to his good people, which should not tend to the breach of the laws of his kingdom and the canons of his church." The sports specified were dancing, archery, leaping, vaulting, May-games, Whitsunales, morrice-dances, and the setting up of May poles. The occasion of this proclamation was the conduct of some Puritan authorities in Lancashire, who, in illegally suppressing, instead of regulating, the customary recreations of the common people, had excited much discontent, and increased the influence of the Roman Catholics by giving a repulsive aspect to the reformed religion. Although the declaration was ordered to be read in the parish churches of the diocese of Chester, this order was not enforced, and the king's design was allowed to drop. Among the excepted unlawful sports were bear-baiting, bull-baiting, bowling, and interludes. Non-conformists and others not attending divine service at church were prohibited from joining in the sports, nor was any one allowed to go out of his own parish for that purpose, or to carry offensive weapons. By republishing this declaration in 1633, and enforcing with great severity the reading of it by the clergy in their churches (see **SABBATH**), Charles I. and Laud excited among the Puritans a degree of indignation which contributed not a little to the downfall of the monarchy and the church. In 1644 the long parliament ordered all copies of it to be called in and publicly burned.—Heylin's *Hist. of the Sabbath and Life of Laud*, Fuller's *Church History*, D'Israeli's *Life of James I.*, Southey's *Book of the Church*, Hallam's *Constitutional History of England*, and Cox's *Literature of the Sabbath Question*.

SPOTSWOOD, ALEXANDER, 1676-1740 ; b. Tangier, Africa ; a soldier of the British army; he served with Marlborough, was wounded at Blenheim. He was governor of Virginia, 1710-22; deputy postmaster-general, 1730; and in 1739 commander of the forces to be sent into Florida. He was active in promoting the cause of education, and especially solicitous for the interests of William and Mary college. He was also interested in the improvement of the condition of the Indian race. It is to his efforts that the improvement in the production of tobacco is attributable, and he favored the act for making tobacco-notes a circulating medium. He introduced the manufacture of iron into Virginia, and explored the Appalachian range of mountains.

SPOTTED-FEVER. See **MENINGITIS**.

SPOTTISWOOD, JOHN, Archbishop of St. Andrews, son of John Spottiswood, superintendent of Lothian, was born in the year 1565. He was educated at the university of Glasgow, and on his father's death, succeeded him as parson of Calder. In 1601, he attended the duke of Lennox as chaplain, when that nobleman was sent as ambassador to France by King James VI. When James succeeded to the English crown, Spottiswood accompanied him on his journey to London, and, soon after that event, on the death of Archbishop James Beaton, was appointed to the see of Glasgow. He was chosen moderator of the general assembly of the Scottish church, which met at Glasgow in 1610, and completed the establishment of episcopal government, which James had labored so long to accomplish. In October of that year, he was along with the bishops of Brechin and Galloway, consecrated at London House by the bishop of London and other English prelates. In 1615, he took a leading part in the examination of John Ogilvie, a Jesuit priest, who was apprehended at Glasgow, and hanged for refusing to disown the temporal power of the pope. The share he took in this matter was most discreditable to the archbishop. In the course of the same year, he was translated to the see of St. Andrews. As primate of the Scottish church, Spottiswood had now the chief management of ecclesiastical affairs, and great influence also in the civil government, and his rule was marked by uniform ability, and, with rare exceptions, by prudence and moderation. He presided at the assembly which met at Perth in 1618, and sanctioned the five points of ecclesiastical discipline known as the Perth articles. He was as much in favor with King Charles I. as he had been with King James, and at the coronation of that sovereign at Holyrood in 1633, he placed the crown on his head

and anointed him. In 1635, Spottiswood was made chancellor of Scotland, a dignity which no churchman had held since the Reformation; but in accepting an appointment so invidious to the nobles, he did not act with his usual discretion. He reluctantly entered into the king's unwise measures for the introduction of a liturgy into Scotland, and became one of the chief objects of popular dislike when the covenanters acquired the ascendancy. He soon found it necessary for his safety to retire to England, and at the end of 1638, at the king's request, he resigned the chancellorship. He protested against the lawfulness of the general assembly which met at Glasgow in November of the same year, and was deposed and excommunicated by that body for alleged offenses, which, so far as his private character was concerned, were improbable in themselves, and supported by no evidence whatever. The archbishop did not long survive the overthrow of the polity which it had been the work of his life to build up. He died at London, Nov. 26, 1639, being then in the 74th year of his age. He had expressed a wish to be buried at Dairsie in Fife, where he had rebuilt the church after the English model, but this was found impracticable, and he was interred in Westminster Abbey. The writings of Spottiswood are his well-known *History of the Church of Scotland*, first published in 1655; a sermon preached at the meeting of the Perth assembly of 1618, which was published by bishop Lindsay in 1621 in his account of the proceedings of that assembly; and a Latin treatise, *Refutatio Libelli de Regimine Ecclesie Scoticanæ*, written in answer to a tract of Calderwood's, and published in 1620. The chief authorities for the biography of the archbishop are the life ascribed to bishop Duppa, prefixed to the folio editions of his *History*, and the life by bishop Russell, prefixed to the Spottiswood society edition of the same work.

SPOTTISWOODE, WILLIAM, 1825-1883; b. and d. London. He graduated at Oxford, 1847; distinguished as a mathematician and as an oriental scholar. He traveled in E. Russia, 1856, and published an account of his travels, and a number of papers upon mathematical and scientific subjects. He was pres. of the London royal soc.

SPOTTSYLVANIA, a co. in n.e. Virginia, intersected by the Richmond, Fredericksburg and Potomac, and the Potomac, Fredericksburg and Piedmont railroads; 400 sq.m.; pop. '90, 14,233, chiefly of American birth. Co. seat, Spottsylvania.

SPOTTSYLVANIA COURT-HOUSE—BATTLES. See WILDERNESS.

SPRAGUE, CHARLES, 1791-1875; b. Mass.; leaving school at an early age became merchant's clerk, and in 1816 a partner; teller in State bank, 1820; cashier of Globe Bank, 1825-65; received, 1821, the prize for the best prologue at the opening of Park Theatre, New York; afterwards prize for the five best poems for the American stage; wrote prize ode for the pageant in honor of Shakespeare at Boston Theatre, 1823; was a member of the city council, and delivered the oration, July 4, 1825; gave an address on temperance, 1827; the Phi Beta Kappa poem, *Curiosity*, at Cambridge, 1829; an ode at centennial celebration of settlement of Boston, 1830. Among his best pieces are *Ode on Shakespeare* and *Winged Worshipers*. An edition of his poems and prose writings appeared in 1855.

SPRAGUE, WILLIAM, 1799-1856; b. R. I.; elected to the state assembly at an early age, and its speaker in 1832. He was a member of congress 1835-37 and U. S. senator 1842-44. He was an extensive manufacturer of cotton.

SPRAGUE, WILLIAM, b. R. I., 1830; succeeded to his father's immense business in the manufacture of calico prints. He was governor of Rhode Island, 1860-63, took part in the war of the secession, and was U. S. senator from Rhode Island, 1863-75. He married a daughter of Chief-justice Chase.

SPRAGUE, WILLIAM BUELL, D.D., 1795-1876; b. Conn.; graduated at Yale college, 1815; private tutor in Virginia, 1815-16; studied at Princeton college and was settled over the First church (Congregational), West Springfield, Mass., as colleague pastor, 1819, and as pastor, 1821; pastor of Second Presbyterian church, Albany, 1829-69; resided at Flushing, L. I., from 1869 until his death. Published numerous sermons and addresses: *Letters to a Daughter*; *Lectures to Young People*; *Letters from Europe*; *Life of Edward Dorr Griffin*; *Life of Timothy Dwight*; *Lectures on Revivals*; *Hints on the Intercourse of Christians*; *Women of the Bible*; *Visits to European Celebrities*; *Annals of the American Pulpit*, 9 vols., a work of great research. He contributed to the biographical department of *Appleton's Cyclopædia*.

SPRAIN. A sprain or strain is a term employed in surgery to designate a violent stretching of tendinous or ligamentous parts with or without rupture of some of their fibers. Sprains are very frequent in all the joints of the upper limbs, especially in the wrist and the articulations of the thumb. In the lower extremity the ankle is the joint by far the most frequently affected; and this is accounted for anatomically by the small size of the articular surfaces, the great weight the astragalus (the bone presenting the lower articular surface) has to support, and the unyielding nature of the lateral ligaments. In slight sprains of this joint the ligaments are only stretched or slightly lacerated, but in more severe cases they may be completely torn through. Sprains of the ankle are sometimes mistaken for fractures, and *vice versa*; and the two

injuries may co-exist. The pain and swelling sometimes make an accurate diagnosis difficult, especially if the patient is not seen for some time after the accident; and if any doubt exists, the case should be treated as for the more severe injury, since it is better that the treatment should be prolonged than that the patient should be maimed; and, fortunately, that which is the proper treatment of a fracture is the best that can be employed for a sprain. Sprains of the knee are not uncommon, and are characterized by great swelling from effusion of fluid within the joint. Sprains of the back are not unfrequent accidents, and are the most serious of any, but in most cases it may be anticipated that after confinement in bed or on a sofa for two or three weeks, and with proper treatment, the patient will be able to walk, although he may feel stiffness and pain for several weeks longer. The treatment of sprains generally must be regulated by their severity. In a severe sprain, attended with much pain and inflammation, leeches should be applied, followed by hot-water fomentations, or the application of a hot linseed-meal poultice. In slighter cases, rest and cold lotions constitute sufficient treatment. In all cases of sprain of the extremities, thin pasteboard splints placed on the outer and inner surfaces of the joint, over a wet bandage previously laid round it, afford support to the part and comfort to the patient. In sprains of the back, more decided antiphlogistic or lowering measures are required. "After an active mercurial purge, a dose or two of Dover's powder may be given, with salines at intervals. The diet ought to be spare. In those of vigorous constitution the abstraction of blood may be required. Afterward, nothing will conduce more to the comfort of the patient than well-managed fomentation of the back. Amendment will be denoted by the patient's turning in bed more freely, and seeking to sit up. At that period stimulating liniments, or the application of the compound tincture of iodine, will be called for. When able to walk, he will be benefited by a warm plaster to his loins."—Shaw on "Injuries of the Back," in Holmes's *System of Surgery*, vol. ii. p. 202.

SPRAINS, or STRAINS, are very common among horses, owing to the severe exertions required of them, often while they are young, and unprepared for such work. Various muscles, ligaments, and tendons are liable to strain, but none more frequently than the large tendons passing down the back of the fore-limbs. In slight cases, cold water continuously applied for several hours gives relief; but in all serious cases, diligent fomentation with water about the temperature of 100° is preferable; or the injured part may be swathed in a thick woolen rug, kept constantly moist and warm by frequent wetting with the hot water. Perfect rest is essential, and in order to insure the relaxation of the large tendons of the horse's limbs, he may in bad cases be kept slung for several days. Blisters, hot oils, firing, and all such irritants, are on no account to be used until the inflammation abates, and the part becomes cool, and free from tenderness. Such remedies are then useful for causing the re-absorption of swelling, and perhaps also for invigorating the weakened part.

SPRAT, *Harengula sprattus*, formerly *Clupea sprattus*, a fish of the family *clupeidæ*, very abundant on many parts of the British coast, and elsewhere in the northern parts of the Atlantic. It is smaller than the herring, being only about six inches in length when full grown, but much resembles it. It is, however, easily distinguished by the serrated belly, and by the position of the fins, the ventral fins beginning immediately beneath the first ray of the dorsal fin, and not beneath the middle of it, as in the herring and pilchard. Another easily observed distinction is the want of axillary scales to the ventral fins, which both the herring and pilchard have. The dentition is also different, and on this account Valenciennes has constituted, for the sprat and a number of other species, the new genus *harengula*, characterized by having teeth on the jaws, tongue, palatines, and pterygoids, but no teeth on the vomer. The herring has teeth on the vomer. Valenciennes states also that the sprat has only 48 vertebræ, whilst the herring has 56. Notwithstanding all this, an old opinion has recently been revived, and urged with some pertinacity on public attention, that the sprat is the young of the herring, which, therefore, it is injurious to a more important fishery to capture. Except that it is not common to find sprats full of roe, nothing has been stated in support of this notion more to the purpose than that the serratures of the belly may possibly be a provision for the growth of the fish; a provision to which it may be remarked that nothing analogous appears in any province of nature. Nor is it wonderful that many sprats may be examined without roe being found, as the greater part of those taken on our coasts have not attained their full size. Sprats abound especially on the coasts of Norfolk, Suffolk, Essex, and Kent in November and several following months. The net used for their capture has smaller meshes than the herring-net. Drift-net fishing is practiced as for herring, and a method called *stow-boat* fishing in which a large bag-net is suspended between two horizontal beams beneath the boat, and about a fathom from the bottom of the water; ropes from the ends of the upper beam enabling the fishermen in the boat to keep the mouth of the bag always open and against the tide. Vast quantities of sprats are taken in this way, so that they are used as manure by farmers, although London is also very largely supplied with them, and being sold at a very cheap rate, they are a favorite article of food of the poorer classes. The firth of Forth also produces sprats—in Scotland, called *garvies*—so abundantly that they are sold both in Edinburgh and Glasgow by measure, and cheaper than any other kind

of fish. But there are many parts of the British coast where the sprat is rare, some of these being parts where the herring is plentiful. Notwithstanding its cheapness, the sprat is a very fine fish, of flavor quite equal to the herring, although decidedly different. Dried sprats are a very common article of provision, and sprats are also sometimes salted. The *kilkie*s brought from Riga and other ports on the Baltic, are sprats cured with spices; and many of the boxes of *sardines* which are sent to market from the west coast of France, are really filled with sprats. The value of the sprat does not seem to be as yet fully appreciated in Britain. Very closely allied to the sprat is another fish (*Harengula latulus*), the *blanquette* of the French, which is caught in great abundance on some parts of the west coast of France. Other species of *Harengula* are found in other seas. One of them (*H. humeralis*), which abounds in the West Indies, and southward as far as Rio Janeiro, is much esteemed, but becomes dangerous at certain seasons, from some unknown cause.

SPRAT, THOMAS, D.D., 1636-1713; b. England; graduated at Oxford; fellow of the Royal society, chaplain to the duke of Buckingham and to Charles II.; canon of Windsor, 1680; dean of Westminster, 1683; bishop of Rochester, 1684; dean of the chapel-royal, 1685; one of the commissioners for ecclesiastical affairs in the reign of James II. In 1692 an attempt was made to implicate him in treason, but he was acquitted. He published *History of the Royal Society*; *Life of Cowley*; *Answer to Sobiere*; *History of the Rye-House Plot*.

SPRENGER, ALOYS, b. Nassereit, Tyrol, 1813; studied medicine and oriental languages at Vienna; entered the service of the East India company; pres. of the college of Delhi in 1845; editor of a Hindustani weekly, *Kiran Alsadain*, and the *Bibliotheca Indica*; was in 1850 government interpreter, secretary of the Asiatic society, and examiner at the College of Fort William in Calcutta. In the *Bibliotheca Indica* he published translations from the Arabic and Persian; also *Life of Mohammed*. In 1858 he was appointed professor of oriental languages at Bonn, and published *Das Leben und die Lehre des Mohamed*, 3 vols. His extensive oriental library was bought by the Royal library in Berlin. He d. 1893.

SPREAD EAGLE. See **EAGLE**.

SPREE, a river of Prussia, rises near Ebersbach in the e. of Saxony, on the borders of Bohemia, and after an irregularly winding, but generally n. and n. western course of 200 m., falls into the Havel (q. v.) at Spandau. It has all the peculiarities of a stream flowing through a low and marshy region—abounding in fish, and frequently expanding into lakes, the largest of which are the *Schwiebelsee* and *Müggelsee*. Its banks are flat, sometimes sandy and wooded, and sometimes rich in meadow pastures. It becomes navigable for small craft at Kosenblatt. The principal towns past or through which it flows are Bautzen, Spremberg, Kottbus, Lübben, Beeskow, and Berlin. Its trade is very considerable. By the Friedrich Wilhelm's or Müllrose canal, it is connected with the Oder.

SPRING, a stream of water issuing from the earth. The source of springs is the rain and snow that falls from the clouds. Very little of the water precipitated in any district finds its way immediately by rivers to the sea; the great proportion is either evaporated from the surface of the earth, and, reabsorbed by the atmosphere, is employed by plants and animals, or sinks into the earth. All loose soils and gravels greedily absorb water, which descends until it meets with a stratum through which it cannot penetrate. A pit dug into the water-charged soil would speedily fill itself by draining the water from the soil. All rocks contain water; some retain it by capillary attraction, like a sponge, others hold it merely mechanically, and easily part with it. Chalk will absorb and retain one-third of its bulk of water; and sand, on the other hand, while it will absorb as much, will part with nearly the whole amount to a well dug in it. Argillaceous deposits and compact rocks are barriers to the passage of water, and cause the superincumbent pervious strata to become water-logged, where there is no outlet. Sometimes the edges of the strata are exposed on the sides of a valley, and permit the free escape of the contained water, which pours from them over the neighboring land. But rents and fissures, as well as inequalities on the surface of the impervious beds, give the water a circumscribed course, and cause it to issue in springs.

The water, as it percolates through the earth, always becomes more or less charged with foreign matter, owing to its solvent property. Carbonate, sulphate, and muriate of lime, muriate of soda, and iron, are the most common impurities in spring-waters; magnesia and silica also frequently occur. These substances, from the evaporation of part of the water, or the escape of the carbonic acid gas, by which so large a quantity is often held in solution, are frequently deposited on the margins of the springs, or in the courses of the streams flowing from them. Such deposits are found in all so-called petrifying springs; and the hot wells of Iceland and the Azores are surrounded with basins formed of siliceous sinter which has been derived from the water. When the foreign ingredients have medicinal qualities, the springs are known as mineral waters (q. v.).

Springs are either associated with the superficial strata, or rise from a considerable

depth. *Surface-springs* occur where the absorbent surface-deposits rest on an impervious bed, which prevents the further downward progress of the water, or where the beds through which the water flows are near the surface, as shown in the fig. where C and E are impervious clay-beds, and D is a bed of sand or gravel, which in the upper portion is exposed on the surface, or is only overlaid by loose soil, and after being covered for some distance by the clay bed C, makes its appearance again at B, where the valley cuts it through; here the

water collected over the area, A, is discharged. Surface-springs, depending as they do so directly on the rain for supplies, are very variable in the amount of water they deliver. They frequently fail entirely in the summer, and always after great droughts. Their temperature varies with that of the district where they exist, being warm in summer, and cold in winter, as they do not penetrate below that plane in the earth's crust which is affected by the seasonal changes in temperature.

When the bed which forms the reservoir for the spring is at such a distance from the surface as to be beyond the zone of season changes, and yet within that which is influenced by the climate, the water has a temperature equal to the mean temperature of the locality where it springs. Such springs have generally a large area for the collection of the superficial water, and are consequently regular in the quantity of water they give out. They are brought to the surface by means of faults. The celebrated well of St. Winifred at Holywell, in Flintshire, rises through a fault in the coal measures. It discharges at the rate of about 4,400 gallons per minute, being the most copious spring in England, and the water, in its short course of little more than a mile to the sea, is used to propel 11 mills.

Most deep wells have a lower origin than the zone of climate temperature, which in Britain is between 200 and 300 feet. It is well known that a regular increase in the temperature is observed after this zone is passed, equal to 1° of Fahr. for every 55 feet. As wells have a temperature corresponding to that of the strata from which they spring, it follows that the deeper the spring the higher will be its temperature. Local conditions may affect the thermal state of springs, as in the case of the Geysers in the active volcanic district in Iceland, and the warm springs near Naples; but where no such local influences exist, the depth of the bed from which the water comes may be to some extent estimated by its temperature. Thermal springs occur in Britain at Matlock (66° Fahr.) and Buxton (82°) in Derbyshire, at Bath (117°) in Somerset, and at Clifton (76°) in Gloucestershire. Artificial communications have been opened with deep-lying strata, by which the water they contain has been brought to the surface, and in these the temperature is found to increase in proportion to the depth of the bore. See ARTESIAN WELLS. The most remarkable thermal springs are the Geysers of Iceland, which are fully described under GEYSER.

Intermittent springs are sometimes produced by the ebb and flow of the tide, as at Richmond, where the rise at high water is seen in the wells which flow from the arenaceous strata on the banks of the Thames; and sometimes they depend on the supply of rain-water. But there is a kind of spring the intermittences of which are believed to be owing to the structure of the internal cavities from which the supply is obtained. A large reservoir is fed by the rain percolating through the rock. It communicates with the surface by a siphon-shaped tube. As long as the water in the reservoir is at a lower level than the arch of the siphon, no water can escape; but as soon as it reaches its level, the whole of the water in the cavity will be drawn off, the spring will then cease, and will only make its appearance when sufficient water has accumulated to permit the siphon again to act.

SPRING, GARDINER, D.D., 1785-1873; b. Mass.; graduated Yale college, 1805; studied law with Judge Dagget, New Haven; taught school two years in Bermuda; admitted to the bar, New Haven, 1808; practiced a year; studied theology at Andover theological seminary, receiving calls while there from the South Parish and Park street church, Boston; was licensed to preach, 1809; ordained pastor of the Brick Presbyterian church, New York, 1810. He declined the presidency of Hamilton and Dartmouth colleges. Of his numerous publications, the following are the most prominent: *Essays on the Distinguishing Traits of Christian Character*; *Fragments from the Study of a Pastor*; *Obligations of the World to the Bible*; *The Attraction of the Cross*; *The Bible not of Man*; *The Power of the Pulpit*; *The Mercy Seat*; *First Things*; *The Glory of Christ*.

SPRING, SAMUEL, D.D., 1746-1819; b. Mass.; graduated at Princeton college, 1771; licensed to preach, 1774; chaplain in continental army, 1775, and accompanied Arnold's expedition to Canada; ordained pastor of a church at Newburyport, 1777, where he remained till his death. He aided in forming the Massachusetts missionary society, 1799, of which he was president; was the primary agent in the establishment of Andover theological seminary, and was prominent in the organization of the American board in 1810. Besides several controversial works, he published 25 miscellaneous discourses.

SPRING-BALANCE, THE, for determining the weight of bodies, consists of a spring in the form of a cylindrical coil, through which passes freely a graduated bar, having a hook attached to its under end, and a plate to its upper. The spring is inclosed in an oblong or cylindrical box, quite closed except at the bottom, where there is a hole just large enough to allow the free passage up and down of the graduated bar. When the instrument is to be used, it is suspended by a ring fastened to the upper part of the box; the weight to be estimated is then hung on the hook, and pulls down the rod, the button or plate at the top of which compresses the helical spring within against the bottom of the box; and the graduation corresponding to this amount of compression of the spring is read off at that part of the rod which just shows itself outside. In another form of the spring-balance, known as Salter's balance, a brass index-plate is attached to the side of the box, and a vertical slit through both plate and box is made from top to bottom; the weight is in this case read off on the plate by a pointer fastened to the spring, and protruding through the slit. In a third form, known as Martin's "index weighing-machine," the interior rod, instead of being graduated, is furnished with a rack on one side; this rack moves a toothed wheel fastened on the side of the instrument; and this wheel, again, has at one extremity of its axis a long index, which, on the wheel being put in motion, traverses a circular dial-plate, on which the graduations of weight are marked. The advantage of this last construction consists in the arrangement of the size of the toothed wheel to that of the dial-plate, so that, since the toothed wheel and index make a complete revolution simultaneously, a small motion of the former may produce a large motion of the latter, and the weight of the body be much more accurately read off than can be done directly on the graduated rod. The spring-balance has one advantage over the ordinary balance, that it does not estimate unknown weight by that which is known, and is therefore applicable to the determination of "absolute" weight in all latitudes, at the equator as well as at the poles; but it has the great disadvantage of being considerably affected by change of temperature, the force of the spring to resist compression being diminished as the temperature increases at the rate of $\frac{1}{5000}$ for each degree of Fahrenheit, and consequently the apparent weights of bodies must be corrected in this proportion. Various other forms of springs, semi-circular, elliptical, etc., are employed, instead of the helical spiral, in several French balances, but in other respects the instruments correspond. The spring-balance is also called a "dynamometer," from its being employed to indicate the intensity of the forces exerted by animals or machines; for this purpose, it is attached between the force and its object, the force being applied to its object solely through the medium of the dynamometer.

SPRINGBOK, *Antelope euchore*, or *Antidorcas euchore*, a species of antelope, nearly allied to the gazelles, very abundant in south Africa. It is an extremely beautiful creature, of graceful form and fine colors. It is larger than the roebuck, and its neck and limbs much longer and more delicate. The general color is fulvous brown on the upper parts, pure white beneath, the colors separated on the flanks by a broad band of deep vinous red. The whole head is white, except a broad brown band on each side from the eye to the mouth, and a brown spot in the center of the face. Two curious folds of skin ascend from the root of the tail, and terminate near the middle of the back; they are usually closed, but open out when the animal is bounding, and disclose a large triangular white space which is otherwise concealed. The springbok derives its name from the prodigious leaps which it takes either when alarmed or in play, often to the height of 7 ft., and sometimes of 12 or 13 ft. Its ordinary residence is in the *karroos* or arid sandy plains; but when all pasture there is burned up, immense herds congregate together, and migrate to more fertile regions, often devastating the fields of the colonist. Mr. Pringle speaks of seeing the country near the Little Fish river specked with them as far as the eye could reach, and estimates the number in sight at once as not less than 25,000 or 30,000. Capt. Cumming describes a still more extraordinary scene, a vast herd pouring through an opening among hills, in one living mass, half a mile in breadth, and so continuing for hours together. So dense are these herds sometimes in their migrations that the lion or the leopard, which ordinarily hangs on their skirts with a view to prey, is taken prisoner, and compelled to march along in the midst.

SPRINGER, WILLIAM M., b. Sullivan co., Ind., 1836. He removed with his parents to Ill., 1848; graduated at the Ind. state univ. 1858, and at law 1859; was sec. of the Ill. constitutional convention 1862, and a member of the state legislature 1871-72. He was a member of congress from Illinois, 1875-95; chairman of the ways and means committee, 1891-93.

SPRINGER. See ARCH.

SPRINGER, a kind of dog, regarded as a variety of the Spaniel (q.v.). It is small, elegant, usually white, with red spots, black nose and palate, long pendent ears, and small head. Its aspect is very lively, and its manners equally so. It is used by sportsmen for raising game in thick and thorny coverts. There are several breeds or sub-varieties.

SPRINGFIELD, city, capital of Illinois, and co. seat of Sangamon co.; on the Baltimore and Ohio Southwestern, the Chicago and Alton, the Chicago, Peoria, and St.

Louis, the Illinois Central, the St. Louis, Chicago, and St. Paul, the St. Louis, Peoria, and Northern, and the Wabash railroads; 190 miles s. of Chicago. The city has a beautiful location on a prairie, is about 5 miles s. of the Sangamon river, and is laid out regularly, with streets crossing at right angles. There are electric lights and street railroads, waterworks supplied from wells by direct pressure, several national and state banks, about 35 churches, and daily, weekly, and monthly periodicals. The noteworthy buildings include the state capitol, U. S. government building, governor's mansion, state arsenal, co. court-house, city hall, the former residence of President Lincoln, the superb national monument to his memory in Oak Ridge cemetery, the St. John's and Wabash Railroad hospitals, and the Prince sanitarium. The city has public school property valued at \$300,000, and, among educational institutions, Concordia college (Lutheran), St. Agatha's school (P. E.), Bettie Stuart institute (non-sect.), and several Roman Catholic convent and parochial schools. Besides the school library there are the public, the state historical, the state, and the state museum of natural history libraries. The city is the seat of a Protestant Episcopal bishopric. The U. S. census of 1890 reported for Springfield, 374 manufacturing establishments, employing \$3,641,415 capital and 3,269 persons, paying \$1,745,158 for wages and \$3,790,754 for materials, and having a combined output valued at \$6,562,470. The principal industrial plants are rolling mills, machine shops, plow works, watch factory, furniture factory, and more than a dozen coal shafts. Pop. '90, 24,963.

SPRINGFIELD, city and co. seat of Hampden co., Mass.; on the Connecticut river, the Boston and Albany, the Boston and Maine, the New England, and the New York, New Haven, and Hartford railroads; 99 miles w. of Boston. It contains the villages of Brightwood, Indian Orchard, and Sixteen Acres; was known as Agawam by the Indians; was settled in 1635 by parties from Roxbury, and organized as a town in 1636; was burned by the Indians in 1675; and was made a city in 1852. The city is beautifully situated, partly on level ground, and from its highest part, Arsenal hill, a fine view of the Connecticut valley is obtained. Its streets are shaded with large and old trees. The river is crossed at this point by bridges connecting with West Springfield and Agawam. There are several cemeteries; Forest park, Hampden park, containing race tracks; and on Armory Hill a park of 72 acres, in which is situated the U. S. armory. The city is lighted by electricity; and has electric street railroads connecting with Chicopee, Chicopee Falls, and Holyoke; and is supplied with water from the Ludlow reservoir. It is the seat of a Roman Catholic bishopric, and contains over 40 churches, the Congregational predominating. Over \$1,000,000 is invested in public school property. The educational institutions include the French-American college, International, Y. M. C. A. training school, school for Christian workers, industrial institute, and high, grammar, and other public day and evening schools. Among the noteworthy buildings are the U. S. armory, U. S. government building, high school, art museum, Y. M. C. A. building, Court Square theater, Union depot, co. court house, public library, soldiers' monument, and the statue of *The Puritan*, in Stearns park, a memorial to Samuel Chapin, one of the early settlers of the city. The U. S. census of 1890 reported for Springfield, 692 manufacturing establishments, employing \$13,199,283 capital and 10,250 persons, paying \$5,868,894 for wages and \$7,817,534 for materials, and having a combined output valued at \$17,040,692. Besides the U. S. armory, the principal industrial plants are the Smith and Wesson revolver works, the Wason railroad car shops, and extensive manufactories of envelopes, bicycles, cotton and woolen goods, locomotives, boilers, iron bridges, machinery, skates, etc. There are over 15 national, savings, and co-operative banks, and trust companies, and a large number of daily, weekly, and monthly periodicals. Pop. '90, 44,179.

SPRINGFIELD, city and co. seat of Greene co., Mo.; on the St. Louis and San Francisco and the Kansas City, Fort Scott, and Memphis railroads; 130 miles s. of Jefferson City. The city is built on the summit of the Ozark mountains, in a rich zinc and lead region, has a mild and healthful climate, and is near the battle-field of Wilson creek, where Gen. Lyon, of the union army was killed during the civil war. It is regularly laid out, and has a supply of excellent water from mountain springs, electric lights, electric street railroads, national and state banks, about 20 churches, and daily, weekly, and monthly periodicals. There are a U. S. government building, national and confederate cemeteries, St. John's hospital, Drury college (Cong.), high school, Y. M. C. A. (the three last with libraries), and a normal school. Over \$1,500,000 is invested in manufactories, which have an annual output of over \$3,000,000. The two railroads passing through the city have each extensive construction and repair shops, and there are also iron works, foundry, and wagon and furniture factories. Pop. '90, 21,850.

SPRINGFIELD, city and co. seat of Clarke co., O.; on Mad river and the Cleveland, Cincinnati, Chicago, and St. Louis, the Erie, the Ohio Southern, and the Pittsburg, Cincinnati, Chicago, and St. Louis railroads; 45 miles w. of Columbus, the state capital. It derives good power both from the Mad river and the Lagonda creek, which passes through the city and park, and manufacturing is largely promoted thereby. The U. S. census of 1890 reported for Springfield 372 manufacturing establishments, employing \$14,567,931 capital and 6,693 persons, paying \$3,195,441 for wages and \$4,752,062 for materials, and having a combined output valued at \$10,760,965. The distinctive industry of the city is the manufacture of agricultural implements, particularly reapers,

mowers, cultivators, and grain drills. Other important manufactures are steam road rollers, piano plates, bicycles, rubber tire wheels, metal wheels, gray iron and malleable castings, iron bridges, electric power plants, water wheels, steam and lawn mowers, gas engines, emery wheels, etc. The city is the seat of Wittenberg college (Lutheran), and has a seminary, business college, Mitchell-Thomas hospital, Warder public library, U. S. government building, municipal building, co. court-house, Children's home, State Masonic home, State Pythian home, State Odd Fellows' home, Lagonda club house, Snyder park, and Fern Cliff cemetery. There are gas and electric light plants, electric street railroads, waterworks belonging to the city with a capacity of 12,000,000 gallons per day, about 45 churches, several national banks, savings banks, and many daily, weekly, and monthly periodicals. Pop. '90, 31,895.

SPRINGFIELD, a township in Hamilton co., O.; containing Glendale, Hartwell, and Wyoming villages and parts of Arlington Heights, Carthage, and Lockland villages; pop. '90, 10,793.

SPRING GARDEN, a township in York co., Penn. Pop. '90, 5209.

SPRINGS, MECHANICAL, are very variously constructed for different purposes. The simplest form of spring is a piece of elastic metal wire, rolled on a mandrel, so as to form a continuous single cylindrical coil of any length needed. Clock and watch springs are made in flat coils, thin bands of steel being used. The *balance-spring* of watches is, however, made of fine wire often thinner than hair. Coach-springs are formed of a series of curved narrow plates of steel of different sizes, placed one over the other, the largest being at the bottom, and the others in regular succession according to size, the whole being held together with nuts and screws. These are some of the commonest forms.

SPRIT (*spr̄iet*, Dutch; old English verb, *spr̄it*, to sprout or spring out) means a pole or spar. The word occurs most frequently in the compound, bowsprit, which explains itself. When used alone, a sprit is a diagonal yard for sustaining a quadrilateral (usually square) fore-and-aft sail.

SPROAT, EBENEZER, 1752-1805; b. Middleboro, Mass.; called by the Indians *Big Buckeye*; entered the army with the rank of capt., 1775; rose through successive grades to be lieut.col. commanding 2d Mass. regiment. He led his command through the battles of Trenton, Princeton, and Monmouth under Brig.Gen. Glover; was appointed by Gen. Steuben brigade inspector. At the close of the war he took up his residence as a surveyor in Providence, R. I., where he married a daughter of Commodore Whipple. He was land-surveyor of Ohio in 1786; one of the founders of Marietta in 1788; col. of militia and sheriff for 14 years.

SPRUCE. See FIR.

SPRUCE, ESSENCE OF, AND SPRUCE-BEER. The essence of spruce is obtained by boiling the green tops of the black spruce (*abies nigra*) in water, and then concentrating the decoction by another boiling without the spruce tops. The young shoots of this fir, like most others of its family, are coated with a resinous exudation, which is dissolved in the water. The beer is made by adding the essence of spruce to water in which sugar or treacle has been dissolved, in the proportion of about 4 oz. of essence of spruce to 10 lbs. of sugar, or 3 qts. of treacle, and 10 or 11 gals. of water, with about half a pint of yeast.

SPULLER, EUGÈNE, French politician, was born at Seurre in 1835, studied at the Lyceum and at Dijon, and became a member of the Paris bar in 1862. Shortly after he was editor of the *Europe* of Frankfort, and contributed to the *Journal de Paris* and the *Journal de Genève*. In 1868 he was one of the founders of the *Révue Politique*. He strongly opposed the plébiscite of May, 1870, and after the revolution of Sept. 4, 1870, was the confidential friend and secretary of Gambetta. He was principal editor of *La République Française* from 1871 to 1876, when he was elected a Deputy for the 3rd arrondissement of Paris, and re-elected in 1881. In 1887 he became Minister of Public Instruction; in 1889 replaced M. Goblet in the Department of Foreign Affairs, and the same year was elected Deputy from Beaune. He has written *Michelet, sa vie et ses œuvres* (1876); *Ignace de Loyala et la Compagnie de Jésus* (1876); *La Compagnie de Jésus devant l'histoire* (1877); and a collection of his *Conférences* (1879-81); *Figures Disparues* (1886); *Conférence sur la Vie et les Œuvres de François Rude* (1888). D. 1896.

SPUNGING-HOUSES are, in the law of England, the private houses of the bailiffs, who may detain there a debtor who has been arrested for debt for 24 hours, to admit of his or his friends' arranging to settle the debt; and the name is derived from the extortion often practiced in this state on the debtor.

SPUR, an apparatus fastened to the heel of a horseman, for goading the horse. It is much less used than formerly. All cavalry soldiers wear spurs; but their use, except in the heat of an actual charge, is discouraged as much as possible. In the days of chivalry, the use of the spur was limited to knights, and it was among the emblems of knighthood. To win his spurs, was for a young man to earn knighthood by gallant conduct. The degradation of a knight involved the hacking off of his spurs; and the serving before a knight of a pair of spurs on a dish, was a strong hint by his host that he had outstayed his welcome. See illus., ANCIENT ARMOR, vol. I.

SPURGE, *Euphorbia*, a genus of plants of the natural order *euphorbiaceæ*, having monœcious naked flowers, the male flowers membranous, and surrounding a tricocous stalked female flower, the whole placed within a cup-shaped involucre. The fruit has three valves and three cells, the cells one-seeded, and bursting elastically. The species are very numerous, natives of warm and temperate climates, mostly herbaceous, but some of them woody. About 12 species are natives of Britain. All contain a resinous milky juice, which in most is very acrid.

SPURGE-LAUREL. See **DAPHNE**.

SPURGEON, CHARLES HADDON, a celebrated preacher, was b. at Kelvedon, Essex, in 1834. Intended by his family for the office of an Independent minister, his own sympathies drew him toward the Baptists, whose connection he joined in 1850. He became at once an active tract-distributor and school-teacher; and, removing to Cambridge in 1851, began to deliver cottage sermons in the neighborhood. The popularity of the "boy-preacher" was almost immediately established; and at the age of 18 he had charge of a small Baptist congregation in the village of Waterbeach. In 1853 he entered upon the pastorate of the New Park street chapel, London, where his preaching proved so attractive, that, in two years' time, the building had to be greatly enlarged. His hearers continuing to increase, the Surrey music hall was for some time engaged for his use; and finally his followers built for him his well-known "Tabernacle," in Newington Butts, opened in 1861. The evangelistic and philanthropic agencies in connection with this immense chapel comprise the Stockwell Orphanage, of which Spurgeon is president; a pastor's college, where hundreds of young men are trained for the ministry under Spurgeon's care; the Golden lane mission, etc. Spurgeon continued to preach in the tabernacle every Sunday to thousands of hearers. His sermons have been published weekly since 1854, and yearly volumes have been issued since 1856. They have had an enormous circulation, and many of them have been translated into various languages. He also published *John Ploughman's Talk*; *Morning by Morning*, *Evening by Evening*; *The Treasury of David*; *Lectures to my Students*; *The Saint and his Saviour*, etc.; and since 1865 he had edited a monthly magazine, *The Sword and the Trowel*. He died in 1892.

SPURN HEAD, the name given to the extreme point of a long, low, narrow, and shingly peninsula in the s.e. of Yorkshire, at the mouth of the Humber, 24 m. s.e. of Hull. Two light-houses have been built here, one of which is in lat. 53° 34' 7" n., and long. 0° 7' 2" east.

SPURREY, *Spergula*, a genus of plants which has been variously ranked by botanists in the natural orders *caryophyllææ*, *illecebrææ*, and *crassulæææ*. The species are annuals, dichotomously branched, or with whorled branches; their leaves linear-filiform, in clustered whorls, with membranaceous stipules; the flowers in terminal divaricating corymbs. The flowers have a calyx of five sepals, five white petals, five or ten stamens, and five styles; the capsule is five-valved, with numerous round seeds, surrounded with a membranous border. **COMMON SPURREY**, or **YARR** (*S. arvensis*), is plentiful in corn-fields, especially on light stony or sandy soils in Britain and most parts of Europe. In some parts of Europe a larger variety is frequently sown for fodder, and is much relished by cattle.

SPURZHEIM, KASPAR, a German physician and phrenologist, was b. near Treves, Dec. 31, 1776. While studying medicine at Vienna he was introduced to Dr. F. J. Gall (q. v.), whose pupil, and afterward colleague, he became, in investigating the structure and functions of the brain (see **PHRENOLOGY**), in lecturing on the subject, and in writing for the press. In 1807 they settled in Paris, but parted in 1813; and next year Spurzheim came to England, where he published *The Physiognomical System of Drs. Gall and Spurzheim* (Lond. 1815), *Outlines of the same* (1815), and a treatise on *Insanity* (1817). The first of these works having been severely handled by Dr. John Gordon in no. 49 of the *Edinburgh Review*, Spurzheim proceeded to Edinburgh, and, in the lecture-room of his critic, demonstrated the reality of the anatomical discoveries which had been denied and ridiculed. To the same and other opponents, he replied in *An Examination of the Objections made in Britain against the Doctrines of Gall and Spurzheim* (Edinburgh, 1817). It was about this time, and under his tuition, that George Combe (q. v.) became a student of phrenology. After lecturing in many British and Irish cities, Spurzheim returned, in 1817, to Paris; but from 1825 till his death he resided much in England, teaching and defending his opinions in lectures and books. In 1832 he went to America for the same purpose, and began his labors at Boston, but was cut off by fever on Nov. 10 in that year. Besides the English works already mentioned, he wrote: *Elementary Principles of Education* (Edinburgh, 1821; 2d ed., Lond. 1828; French translation, Paris, 1822); *Phrenology* (Lond. 1825); *Philosophical Principles of Phrenology* (1825); *Phrenology in Connection with the Study of Physiognomy* (1826); *Anatomy of the Brain* (1826), supplemented in 1829 by an appendix, with *Remarks on Charles Bell's Animadversions on Phrenology*; *Outlines of Phrenology* (1827); and *Sketch of the Natural Laws of Man* (1828). Some of these were reprinted at Boston. His French works (besides those written jointly with Gall) are: *Obs. sur la Folie* (Paris, 1818); *Obs. sur la Phrénologie* (1818); *Essai Philosophique sur la Nature Morale et Intellectuelle de l'Homme* (1820); and *Manuel de Phrénologie* (1832). See *Phren. Jour.*, vol. viii. p. 126; *For. Quart. Rev.*, vol. ii. p. 15; *Memoir of Spurzheim*, by A. Carmichael (Dublin, 1833); and Combe's *System of Phrenology*.

SPUYTEN DUYVIL CREEK, a channel connecting the Hudson and Harlem rivers and separating Manhattan island, on which the greater part of New York city is built, from the mainland on the n. The construction of the Harlem ship-canal (opened in 1895) comprised the widening and deepening of the channel of the Harlem river and Spuyten Duyvil creek and the cutting of a canal through an intervening neck of land. The canal is 7 miles long, and saves over 25 miles of distance in the traffic between the Hudson river and Long island sound.

SPY, in war, is a useful but not highly honored auxiliary, employed to ascertain the state of an enemy's affairs, and of his intended operations. Spies have been used in all wars from the time when Moses sent Joshua on such a purpose to the present time. Their employment is quite recognized by the law of nations as interpreted by Grotius, Vattel, and Martens; nor is it held to be any dishonor to a general to avail himself of their services. On the other hand, the spy himself is looked upon as an outlaw, and one devoid of honor. If taken by the enemy, he is put to death ignominiously and without mercy. As, however, the calling is so dangerous, and so little redounds to honor, it is never permissible for a general to compel by threats any person, whether of his own or the hostile party, to act as spy; but he is at liberty to accept all such services when proffered. A spy is well paid, lest he betray his employer. In the British army spies are usually controlled by the quartermaster-general. Martial law, though distinct enough in ordering the death of a spy, is not clear in defining what constitutes a spy. A man—not of the enemy—within the enemy's lines, and in the enemy's uniform, would presumably be a spy. If in civil dress, and unable to give a good account of himself, his chance of hanging would be considerable; but if found in one camp in the uniform of the opposite side, he may not be treated otherwise than as a prisoner of war, or at least as a deserter from the enemy.

Both as regards honor and penalties, it would seem that spies ought in fairness to be divided into two classes—first, those who betray their own country to an enemy; secondly, those who, being enemies, contrive surreptitiously to obtain information by penetrating into the opposing army. The first class are traitors of a deep dye, for whom no ignominious death is too bad; but the second class are often brave men, who dare much in the service of their country. It is unfair to accord them the same treatment as the traitors.

SQUAD (diminutive of squadron) is any small number of men assembled for the purposes of drill or inspection. A troop or company of soldiers should be divided into as many squads as there are officers or sergeants at hand to drill them.—The *awkward squad* comprises recruits not yet fitted to take their places in the regimental line.

SQUADRON (Ital. *squadra*, from Lat. *quadra*, a square), in military language, denotes two troops of cavalry. It is the unit by which the force of cavalry with an army is always computed. Three or four squadrons constitute a regiment. The actual strength of a squadron varies of course with that of the component troops; but it ranges from 120 to 200 sabers.

In naval affairs a squadron is a section of a fleet, and constitutes the command of a junior flag-officer or commodore.

SQUALUS AND SQUALIDÆ. See SHARK.

SQUAMIPENNES. See CHÆTODONTIDÆ.

SQUARE, in military evolutions, is the forming of a body of men into a rectangular figure, with several ranks or rows of men facing on each side. With men of ordinary firmness a square should resist the charges of the heaviest horse. The formation is not new, for a Grecian syntagma was a solid square of 16 men in every direction; but in modern warfare the solid square, having been found cumbersome, has been abandoned for the hollow square, with officers, horses, colors, etc., in the center. The front rank kneels, and the two next stoop, which enables five ranks of men to maintain a rolling fire upon an advancing enemy, or to pour in a murderous volley at close quarters.

SQUARE, in geometry. See PARALLELOGRAM.

SQUARE AND SQUARE ROOT are particular cases of *involution and evolution* (q.v.), in which the second power and root are alone involved. The process by which the square root of a number is obtained resembles division, differing only by the circumstance that the divisor is changed at each successive step. The rule adopted in arithmetic is deduced from algebra in the following manner: The square of $a + b$ is $a^2 + 2ab + b^2$, which may be written $a^2 + b(2a + b)$; and to find the square root of the latter we have merely to subtract a portion (a^2), taking care that it be a square number, and forming a divisor with twice the square root of this portion ($2a$) increased by (b) the remainder of the root (which, in arithmetic, must be found by trial, as in division), and putting (b) the remainder of the root now found, in the quotient, proceed as in division. This mode of obtaining a divisor from the part of the root already obtained (a), and the part next to be obtained (b), and employing it, must be repeated till the whole square root is found. In the extraction of the square root in arithmetic it is assumed that the squares of the nine digits are known, and also that the square of a number contains either twice, or one less than twice, as many digits as the number itself contains, the former being the case when the square number has an *even* number of digits, the latter when the number of

digits is *odd*. By dividing, then, a number into periods of two figures each, we can at once see how many digits its root contains. To illustrate the method of operation adopted in arithmetic and algebra, let the square root of 128,881 be required; remembering that the square of $a + b + c$ is $a^2 + 2ab + b^2 + 2(a + b)c + c^2$:

$$\begin{array}{rcl}
 (a^2 =) 300^2 & = & 90000 \\
 12,88,81(300 + 50 \text{ (or } 350) + 9 = 359 & & a = 300 \quad 12,88,81(300 = a \\
 a + b \text{ (or } a + b) + c & & 300 \quad 90000 \quad 50 = b \\
 38881 & & 2a + b = 650 \quad 38881 \quad 9 \\
 2 \times 300 \times 50 + 50^2 = & 32500 & 32500 \quad 359 \\
 2(a + b)c + c^2 & & 2(a + b) + c = 709 \quad 6381 \\
 2 \times 350 \times 9 + 9^2 & = & 6381
 \end{array}$$

In the common arithmetical mode the zeros are omitted, and we subtract from 12 the square nearest to it, not recognizing the portion of the root, 3, as more than a digit of units till the next period, 88, has been brought down for the second step, when it is evident that the 3 is *at least* 3 tens, and consequently the 6 in the divisor represents 60; similarly, it is only at the commencement of the third step that we find the 5 to represent 50, and the 3, 300. A comparison of the above examples will show the agreement and difference between the two modes.

SQUARE-PIERCED, in heraldry, a term used to designate a charge perforated with a square opening, so as to show the field. A cross square-pierced is often improperly confounded with a cross quarter-pierced, where the intersecting part of the cross is not merely perforated, but entirely removed.

SQUARES, METHOD OF LEAST, in astronomy, the best mode hitherto discovered of obtaining the most correct result from a number of observations upon any phenomenon. These observations are assumed to differ slightly from each other, and to be all of equal value, that is, taken under equally favorable conditions, and with equal instruments. The ordinary and long-established mode of approximating to the truth in such cases is by finding the arithmetic mean, and accepting it as the correct result; but in all cases where the result required does not come directly from observation, but requires to be discovered by calculation, this simple and useful method is inapplicable, and that of "least squares," which gives more probable corrections, is adopted. The method is founded on a theorem which was first propounded by Legendre in 1806, more for the sake of insuring uniformity among calculators than from any belief in its intrinsic value; but it was afterward thoroughly discussed and proved, by Gauss and Laplace, that "if the mean of a number of distinct observations be so taken that the sum of the squares of its differences from the actual observations (generally designated *errors*) shall be a minimum, this mean will be, under these circumstances, the correctest obtainable value." For a full view of the whole of this subject, see a paper by Mr. Ellis in the *Cambridge Transactions*, vol. viii.

SQUASH. See **GOURD**.

SQUASH BUG, a hemipterous insect which infests squash, pumpkin, and other like plants. It belongs to the family *coreide*, and is about six-tenths of an inch long and about half as broad; rusty black above, dingy ochre yellow beneath. It emits a strong and offensive odor, which is supposed to be due to the presence of organic formates in the secretions. It passes the winter in crevices and holes, in a torpid state, and when the squash vines put forth a few rough leaves in the spring, it collects beneath them and lays eggs, which it fastens in clusters to the under side. Another kind, the striped squash bug, is a coleopterous insect, *diabrothica vittata*. It is much smaller but more destructive.

SQUATTERS, the name given in the Australian colonies to the sheep-farmers who occupy the unsettled lands as sheep-runs under lease from government. It is applied in the United States to persons who settle on lands to which they have no legal title. See **NEW SOUTH WALES**, **VICTORIA**.

SQUATTER SOVEREIGNTY. See Taylor's Administration in the article **UNITED STATES**.

SQUAW. The native American Indian woman, as found by Columbus and his followers, was in a most degraded state, being in entire subjection to her husband and compelled to perform all the labor of the field and camp, and carry all the burdens. She wore a mantle of feathers, exceedingly warm and handsome, and like her husband, a bead necklace. Her body was tattooed with puceon, which is the blood-root. On hunting expeditions she carried all the implements and built the huts at the end of the long day's march, while the warriors smoked their pipes calmly and looked on, or the youthful braves practised shooting at a target, for by such manly accomplishments they got their wives. Cooking was very simple, the common way being to roast over a fire, without seasoning; baking was done in holes in the ground and water was boiled by placing in it stones intensely heated. Corn was parched and carried with them on hunting expeditions, often being hidden in holes marked for recognition.

SQUAW-MAN is the term applied in the Western territories to a white man who marries an Indian wife. According to the tribal law of the Indians, such a marriage gives the husband all the privileges of a member of the tribe, including an equal share

in the land allotted to it by the government. Such marriages are very common among the frontiersmen, though the squaw-men lose caste with the whites of their acquaintance.

SQUID. See CALAMARY.

SQUIER, EPHRAIM GEORGE, LL.D., American author and archaeologist, was b. at Bethlehem, N. Y., June 17, 1821. In his youth, he was a school-teacher and engineer, and in 1840 was editor of *The Mechanic*, at Albany; in 1843, of the *Hartford Journal*, and in 1844, of the *Scioto Gazette*, in Ohio. His attention being attracted to the antiquities of the Scioto valley, he made an exploration of similar monuments through the Mississippi valley, an account of which was published in 1848, forming the first volume of the *Smithsonian Contributions to Knowledge*. He made similar explorations in New York and Connecticut; and on being appointed *chargé d'affaires* to Guatemala and other states of Central America, he used his official position as a means of making extensive geographical and archaeological explorations in those interesting regions. On visiting Europe in 1851, he was honored with the gold medal of the French geographical society, and made a member of other learned societies. Returning to America (1853), he surveyed a railway route through Honduras, and drew up the treaty between that country and England for the retrocession of the Bay islands. Among his works are—*Nicaragua: its People, Scenery, Ancient Monuments, and Proposed Inter-oceanic Canal* (1862); *The Serpent Symbol, or Worship of the Reciprocal Principles of Nature in America* (1852); *Notes on Central America* (1854); *Waikna, or Adventures on the Mosquito Shore* (1855); *Question Anglo-Américaine* (1856); *The States of Central America* (1857); the report of the Honduras survey (1859); a work on tropical fibers (1861); *Honduras* 1870; *Peru* (1876); articles in the *Encyclopædia Britannica*; etc. He d. 1888.

SQUILL, Scilla, a genus of bulbous-rooted plants of the natural order *Liliaceæ*, nearly allied to hyacinths, onions, etc., and having a spreading perianth, stamens shorter than the perianth, smooth filaments, a 3-parted ovary, and a 3-cornered capsule with three many-seeded cells. Many of the species are plants of humble growth, with scapes like those of hyacinths, and beautiful flowers. Of these, two are natives of Britain: *S. verna*, which is common on the western and northern coasts, and particularly in Orkney and Shetland, and has fragrant flowers of a deep blue color; and *S. autumnalis*, which grows chiefly on the coasts of the s. of England, and has pinkish purple flowers. *S. bifolia* is a very doubtful native of Britain, but adorns hill-pastures and borders of woods in many parts of Europe with its blue flowers in early spring. *S. amana* is another very beautiful species found in many parts of Europe. Few plants are better adapted than these for the adorning of flower-borders, or for house-culture.—Very different in habit from these is the OFFICIAL SQUILL (*S. maritima*, or *Urginea Scilla*), a native of the sandy shores of the Mediterranean, which has a scape from two to four ft. high, with a raceme of many whitish flowers, and large leaves. The bulb is of the size of a man's fist, or sometimes as large as a child's head, and contains a viscid juice so acrid as to blister the fingers if much handled, while the vapor arising from it irritates the nose and eyes. Squill was used in medicine by the ancients, and continues to be so still. The bulb is dug up in autumn, divided into four parts, the center being cut out as being inert, and the remainder being cut into thin slices, which are quickly dried by a gentle heat. It is imported from Malta and other Mediterranean ports; also from St. Petersburg and Copenhagen. The dried slices are white or yellowish white, slightly translucent, scentless, disagreeably bitter, brittle and easily pulverizable if very dry. The chemical composition of Squill is not accurately known, its most active principle being a very acrid, poisonous, resinoid substance, soluble in alcohol, but not in ether. What ever its active ingredients may be, they are taken up by alcohol, vinegar, and the dilute acids. This medicine is prescribed as a diuretic and expectorant, and occasionally as an emetic; but it must be recollected that in moderately large doses it acts as a narcotico-irritant poison, 24 grains having proved fatal. When given as a diuretic, it is usually prescribed in combination with digitalis and calomel, when it seldom fails to produce an increased secretion of urine, while at the same time it promotes the absorption of the effused fluid in the dropsy, which is generally present when diuretics are ordered. Its use is counter-indicated if inflammatory symptoms are present. Its dose as a diuretic is from one to three grains of the powdered bulb, or about twenty minims of the tincture. As an expectorant, it is much employed in the subacute stages and chronic forms of pulmonary affections, and is very serviceable in bronchitis and pneumonia of children. From its property of promoting the secretion of mucus, it gives relief by facilitating the expectoration in cases of asthma, etc., in which the sputa are viscid. In these cases, it is usually associated with some of the more stimulating expectorants, as senega or sesquicarbonate of ammonia. As an expectorant, the dose of the powdered squill should not exceed one grain, repeated several times daily. For children, the syrup, in doses of from 10 to 30 minims, may be given. As its action as an emetic is uncertain, it should not be prescribed with the view of inducing vomiting if other and more certain remedies are at hand.

SQUILLA, a genus of crustaceans, of the order *stomapoda*, the type of a family, *squillidæ*, to which the name *mantis crab*, *mantis shrimp*, and *sea-mantis*, are popularly given,

from the strong general resemblance to the insects of the genus *mantis* (q.v.). The form is elongated; the carapace only covers the anterior part of the thorax, the latter part of which is formed of rings like the abdomen; the eyes are carried on stalks; the claws are very large, and furnished with spines, forming powerful instruments of prehension; the tail is expanded into a broad fin. The species are numerous, and mostly inhabit tropical seas. A species about 7 in. long, *S. mantis*, is found in the Mediterranean. The *squillæ* are extremely active, and very bold and voracious.

SQUINCH, small arches or corbelled courses across the angles of square towers, to bring in the form to carry an octagonal spire, lantern, etc. See PENDENTIVE.

SQUINTING, or STRABISMUS, is a well-known and common deformity, which may be defined as a want of parallelism in the visual axes, when the patient endeavors to direct both eyes to an object at the same time. The squint is said to be *convergent* when the eye or eyes are directed toward the nose, and *divergent* when they are directed toward the temple, and is termed *single* or *double* according as only one eye or both are displaced. The divergent form is comparatively rare, except in consequence of a prolonged loss of sight of one eye. The causes of this affection are various. Intestinal irritation, such as the presence of worms, will often induce it slightly in children. In other cases it may be traced to the temporary cerebral irritation produced by teething; and it is a very common symptom in hydrocephalus and other serious head affections. Among other causes are a want of equal normal visual power in both eyes, in extreme short sight; but from extensive observation with the ophthalmoscope, Mr. Dixon, surgeon to the royal ophthalmic hospital, Moorfields, has come to the conclusion, that "in the great majority of instances of confirmed squint existing in children, the optic nerves themselves are ill-developed, being usually smaller than natural, of a more or less oval form, and of a dusky color."—Holmes's *System of Surgery*, vol. ii. p. 890. If the squint is only temporary, and possibly arises from intestinal irritation, the bowels must be well cleared out, and tonics subsequently given. If it is due to some peculiarity in the visual focus of the eyes, it may be removed by the judicious use of glasses. "In every case," says Mr. Dixon, "a careful ophthalmoscopic examination is the first duty of the surgeon; and he should also take every possible care to ascertain that no organic disease exists in the brain or orbital nerves; and that there is no tumor in the orbit, mechanically burdening the movements of the eye." The surgical operation for the cure of squint consists in the division of the muscle which, by permanently drawing the eye inward or outward, and overpowering its antagonistic muscle, induces the deformity. It is better to dispense with the use of chloroform in this operation if the patient have sufficient nerve to bear the operation without flinching, as in that case the doubt that sometimes arises as to whether the muscle has been sufficiently divided can be at once solved by directing the patient to attempt inversion of the eye; but in the great majority of cases chloroform is found necessary.

SQUINTS, narrow apertures cut in the walls of churches (generally about 2 ft. wide), to enable persons standing in the aisles to see the high altar. These openings are always in the direction of an altar.

SQUIRE, an abbreviated term for esquire (q.v.). The same word is also popularly applied in England to country gentlemen; and in the United States of America to magistrates and lawyers, and sometimes to judges and justices of the peace.

SQUIRREL, *Sciurus*, a Linnæan genus of rodent quadrupeds, now the family *sciuridae*. They belong to the section of rodentia having perfect clavicles, and are further characterized by a long bushy tail; the fore-paws furnished with four toes, which have curved claws, and a tubercular thumb; the hind-legs long, their feet with five toes; two incisors in each jaw; four molar teeth on each side in each jaw, simple, with tuberculous crowns, and a fifth in the front of the upper jaw, which soon falls out. Most of the species commonly carry the tail curved over the body, whence the Greek name *skiouros* (*skia*, a shade, and *oura*, a tail), of which the English *squirrel* is a corruption. The species are numerous, and are found in almost all parts of the world, except Australia; some inhabiting temperate and even cold regions, while some belong to tropical countries. Squirrels are very active and lively creatures, at once shy and pert, very adroit in hiding themselves on the appearance of danger, but resembling monkeys in their inquisitive curiosity. They inhabit woods, and mostly spend their lives in trees, which they climb with wonderful agility, running along the branches, and leaping from tree to tree. Their running is a kind of bounding, and the tail is then stretched out, as it is also in their leaps from branch to branch, which are often to great distances. The flying squirrels are already noticed. Even the true squirrels resemble them in spreading out their limbs and tail to the utmost in leaping, particularly when they descend from a high branch to the ground, and they thus leap from a great height without injury. Some species, however, seldom ascend trees, but burrow in the ground, and are further distinguished by having cheek-pouches, while the tail is shorter than in the tree-squirrels, and its hair not so distinctly arranged in two lateral rows. These *ground squirrels* form the genus *tamias*. All the squirrels feed on fruits and seeds, the young shoots of trees, and other such vegetable substances; although they sometimes vary their diet by plundering birds' nests, and not only sucking eggs, but devouring young birds. They are

also fond of the larvæ of insects. In eating they often sit erect, and hold the food in their fore-paws. The hardest nut presents no difficulty to their sharp strong teeth. Many of the species, and probably all those of temperate and cold climates, lay up stores for winter.—The COMMON SQUIRREL (*S. vulgaris*) of Europe is a beautiful little animal, about 8½ in. in length without the tail, which is fully 6 in. long, besides being apparently lengthened by its long hair. It is brownish-red on the upper parts, and white beneath; the color changes more or less in winter to a grayish-brown, and in northern countries to gray, and even to white. The long hairs which fringe the ears and are drawn up in to a fine point, are longer in winter than in summer. The common squirrel is widely distributed over the northern parts of the old world, and is plentiful in England, and in some of the southern parts of Scotland, into which, however, it is said to have been introduced. It is generally protected and its presence desired in the vicinity of mansions; although it often does considerable injury in plantations by gnawing off the top shoots of trees, particularly of firs and pines. Morning is generally the time of the squirrel's greatest activity, except in winter, when it prefers the warmest hours. Although numbers are often seen together, they live mostly in pairs, which seem to continue attached throughout life. The squirrel makes a beautiful nest of moss, twigs, and dry leaves, curiously interwoven, most frequently in the fork of a tree at a considerable height from the ground. Here the young are produced, three, four, or five at a birth, in the middle of summer. They continue with their parents till the spring of next year. The winter hoards of the squirrel, containing nuts, beech-mast, grain, and the like, are usually in holes in the ground about the roots of trees, not far from its ordinary abode, the same pair of squirrels having often a number of these hoards. The seeds of firs form a very considerable part of the winter-food of squirrels, and to obtain them, the scales are gnawed away from the cones. The squirrel is easily tamed, and is an amusing pet. It is almost in constant motion, except when asleep.—The only other European species is the ALPINE SQUIRREL (*S. alpinus*), a native of the Alps and Pyrenees, about the same size with the common squirrel, deep brown, speckled with yellowish white.—North America abounds in species of squirrels. The GRAY SQUIRREL (*S. migratorius*) occurs in the northern parts of the United States, and as far north as Hudson's bay. It is much larger than the European squirrel, the whole length with the tail being nearly two feet. It is usually light gray, with yellowish-brown head, and longitudinal stripes of yellowish brown, but it is often found almost entirely black. Its habits are very similar to those of the common squirrel, but it is more gregarious. Gray squirrels sometimes visit corn-fields in large numbers, and make great devastation. In Pennsylvania an old law gave a reward of threepence a head for every squirrel destroyed, and in the year 1749 no smaller a sum than £8,000 was paid out of the treasury on this account, so that 640,000 squirrels must have been killed. Hosts of this species of squirrels sometimes leave their native woods, and migrate like the lemming (q.v.) of northern Europe, whether urged by scarcity of food or through some other unknown impulse. These migrations usually occur in autumn, and are regarded with great horror by farmers. The squirrels advance in a straight course; mountains are no impediment, and although they swim with difficulty, they cross large rivers and narrow bays of lakes.—The CAROLINA GRAY SQUIRREL (*S. Carolinensis*) is a rather smaller species, abundant in the south-eastern parts of the United States, where its flesh is highly esteemed. A number of other species are found in different parts of North America, and very beautiful species occur in tropical countries, some of which live mostly in palms.—Of ground squirrels, several species are natives of North America, of which the best known is the CHIPPING SQUIRREL, HACKEE, or CHIPMUNK (*tamias Lysteri*), abundant in almost all the eastern parts of the United States, and as far as 50° n. lat. Its length, with the tail, is fully ten inches; the general color gray, longitudinally striped with black and yellowish white. It derives its name from its *chipping* or chattering cry, which is like that of a young chicken. It seldom ascends trees: and is not troublesome to the farmer, as it does not attack standing corn, but gleans the fields, and feeds on fallen nuts in the woods. It burrows near the roots of trees, and several squirrels generally inhabit one burrow, which is deep and winding, and in which stores are laid up for winter use. In carrying nuts or other food to its retreat, it makes use of its cheek-pouches, cramming and distending them to the utmost.—A very similar species (*T. striatus*) inhabits Siberia. See *illus.*, RODENTIA, vol. XII.

The fur of some of the American squirrels is an article of commerce. It is one of the cheapest kinds of fur.

SQUITCH. See COUCH GRASS.

S'RÂDDHA (from the Sanskrit *s'râddhâ*, faith, belief) is the name of the funeral ceremony of the Hindus, in which balls of food, and water, are offered to the deceased ancestors of the sacrificer, or to the *pitr'is* or manes collectively. It is especially performed for a parent recently deceased, or for three paternal ancestors, and is supposed necessary to secure the ascent and residence of the souls of the deceased in a world appropriated to the manes. But this ceremony is observed also on occasions of rejoicing as well as of mourning; and hence various S'râddhas are enumerated—viz.: 1. S'râddhas which are *constant*, or the daily offerings to the manes in general, and those offered on the eighth lunation of every month; 2. S'râddhas which are *occasional*, as those for a

relative recently deceased, or those to be performed on various domestic occurrences, as the birth of a son, etc.; and 3. *S'râddhas* which are *voluntary*, performed for a special object, such as the hope of religious merit, etc. The proper seasons for the worship of the manes collectively are the dark fortnight or period of the moon's wane, the day of new moon, the summer and winter solstices, eclipses, etc. The presentation of the ball of food to the deceased, and to his progenitors in both lines, is the office of the nearest male relative, and is the test and title of his claim to the inheritance.—See for further detail, H. H. Wilson's *Glossary of Judicial and Revenue Terms* (Lond. 1855), under *S'râddha*.

SRĀVAKA (from the Sanskrit *s'ru*, to hear) is the name of the disciples of Buddha, who, through the "hearing" of his doctrine, and by practicing the four great Buddhist truths, attain to the qualification of an arhat, or Buddhist saint. From among the number of the disciples of Buddha, 80 are called the *mahās'râvakas*, or the great *s'râvakas*. The *s'râvakas* are entitled to the predicate *âryushmat*, or "one possessed of (long) life."

SRUTI (from the Sanskrit *s'ru*, hear, hence, literally, the hearing, or that which is heard) is, in Sanskrit literature, the technical term for all those works which are considered to have been revealed by a deity. It applies, therefore, properly speaking, only to the Mantra and Brâhmana portion of the Vedas; but at a later period, it is applied likewise, if not especially, to the Upanishads. See **VEDA**.

SS, COLLAR OF, a collar composed of a series of the letter S in gold, either linked together or set in close order, on a blue and white ribbon, with the ends connected by two buckles and a trefoil-shaped link, from which hangs a jewel. Such collars have been much worn in England by persons holding great offices in the state, as well as by the gentry of various ranks, from esquires upward. They are of frequent occurrence on sculptured monuments; but the origin of the device has not been satisfactorily explained. Among the numerous conjectures which have been formed regarding its meaning, one is, that the letter S stands for "*souveraigne*," the favorite motto of Henry IV.; others have suggested "*seneschal*;" and M. Planché hints that it may, with equal probability, owe its origin to the swan of the De Bohuns, that badge being found in one of the earliest examples of this collar (1402), pendent round the neck of the poet Gower, in St. Saviour's church, Southwark. The collar had, without doubt, originally a Lancastrian character. Collars of SS are still worn, with certain recognized distinctions, by the lords chief justices, the lord chief baron of the exchequer, the lord mayor of London, the heralds, and the sergeants-at-arms.

STAAL, MARGUERITE JEANNE CORDIER DE LAUNAY, Baroness de, 1684-1750; b. Paris; lady in waiting to the duchess of Maine, with whom she took part in a conspiracy against the duke of Orleans. She was imprisoned in the Bastille, 1718-20. She married baron de Staal in 1735. Her *Memoirs* are well known.

STABAT MATER, a celebrated Latin hymn on the crucifixion, beginning

Stabat mater dolorosa
Juxta crucem lacrimosa
Dum pendebat filius.

The *Stabat Mater* forms part of the service of the Roman Catholic church during passion-week. Its authorship has been assigned to Jacopone, a Franciscan, who flourished in the 13th century. It has been set to music by many composers of eminence. Pergolese's *Stabat Mater*, written by that eminent musician on his death-bed, is justly celebrated for its pathos and expression. Rossini's more secular *Stabat Mater* is also well known to all lovers of music.

STABILITY AND INSTABILITY. When a body rests upon a surface in such a manner that a vertical from its center of gravity falls within the largest polygon which can be formed by joining the various points of contact of base and surface, it will stand; but if the contrary is the case, it will fall, unless extraneously supported. If the base

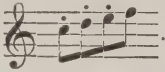

of the body be a plane, and the supporting surface convex, or *vice versâ*, or if both base and surface be convex, there will be only one point of support, and if the body be at rest, its center of gravity must be vertically over the point of contact. Should a body so placed receive a slight impulse, it will either oscillate to and fro, ultimately returning to its original position, or remove further and further from its original position, showing a tendency not to return, or appear indifferent to any one position. In the first case, the body is said to be in *stable*, in the second case, in *unstable*, and in the third, in *neutral* equilibrium. The fig. shows various illustrations of these three species. It will appear at once that the predetermining cause of equilibrium being of one rather than of another of these species, is the tendency of the center of gravity of every body to seek a lower position. In stable equilibrium the center of gravity of the body may, and in unstable equilibrium may not, attain a lower position, while in neutral equilibrium its

position continues unaltered. In illustration of the mode in which the species of equilibrium possessed by a body which has received a slight impulse is determined, let us take the case of a body with a spherical base resting upon a spherical surface (as in fig.); let S and O be the centers of the spherical surfaces respectively, and let A be their point of contact (the center of gravity being consequently in the line SA, or in it produced toward S, and after displacement, in the line S'A', produced if necessary), let the new position of S, after the body has been slightly displaced, be S', and the new point of contact B; join OS, OS', S'A', and draw BD vertically, that is, parallel to OC. Then

$A'D : A'S' :: OB : OS'$, or $A'D = \frac{A'S' \times OB}{OS'}$, that is, $A'D$ = the product of the radii of the two surfaces divided by their sum. Now should the center of gravity of the displaced body fall between D and A', it will have a moment round B tending to restore the body to its former position (*stable equilibrium*); should the center of gravity be beyond D from A', its moment round B will tend to increase the displacement (*unstable equilibrium*); while, if it fall in the line BD, it will still be above the point of contact, as it was at first, and there will be no tendency either to return to, or to move further from, the original position (*neutral equilibrium*). These conditions may be briefly expressed by the following formulæ, in which R is the radius of the supporting surface, r of the spherical base of the body, and X the distance of the center of gravity from the point A; when equilibrium is stable, X is less than $\frac{R \times r}{R + r}$; when unstable, X is greater than $\frac{R \times r}{R + r}$; and when

neutral, $X = \frac{R \times r}{R + r}$. From these formulæ, the conditions of equilibrium of a body, with a spherical base on a plane surface can be at once deduced by making $R = \infty$, the three species of equilibrium being then represented in order by X less than r , X greater than r , and $X = r$; the simplest illustrations of these being respectively a segment of a sphere, a tall cone on a spherical base, and a sphere.

STACCA' TO (Ital. detached), in music, a term implying a detached, abrupt mode of performance. A certain amount of time is subtracted from the proper value of any note played staccato, and a rest substituted. A dot placed over a note indicates that it

is to be played staccato: . A dash implies a greater degree of staccato:

, and a very slight degree of staccato is expressed by uniting the dot

with the slur: ; the slur being the sign of a *legato* expression, the converse of staccato.

STA' CHYS, a genus of plants of the natural order *labiatæ*, containing a great number of species, mostly European, having a ten-ribbed calyx, with five nearly equal teeth, the upper lip of the corolla entire, and the lower lip three-lobed. Several species are natives of Britain. *S. sylvatica* is very common in shady places, a coarse, herbaceous plant, sometimes called *hedge nettle*, with stem 2 to 3 feet high, ovate heart-shaped leaves on long stalks, whorls of purple flowers, and unpleasant smell. *S. palustris* is another very common British species growing in moist places, and sometimes proving a very troublesome weed in meadows. The plant was formerly used as a vulnerary, and has therefore the English name *woundwort*. Several species are not unfrequently to be seen in flower-gardens. To this genus some botanists refer the COMMON BETONY or WOOD BETONY (*S. betonica* or *betonica officinalis*), plentiful in woods and thickets in the southern parts of Britain, a plant one or two feet high, with hairy stem, oblong heart-shaped leaves, whorls of purple or white flowers, and a fetid smell. It was formerly much used in medicine. The roots in small doses, are emetic and aperient.

STADE, a small but very ancient t., formerly fortified, in Prussian Hanover, near the mouth of the Schwinge, a tributary of the Elbe. Pop., abt. 9000.

The *Stade dues* were a toll or duty which used to be charged by the Hanoverian government on all merchandise carried up the Elbe to Hamburg. The original duties, as regulated by a treaty of date 1691, were comparatively light, but they had been gradually increased until they brought to Hanover a revenue of \$200,000. After several modifications in 1844 and 1854, this vexatious toll was finally abolished in 1861, Hanover receiving a compensation equivalent to \$150,000 annually, of which Great Britain paid one-third, another third was contributed by Hamburg, and the remaining third divided proportionally among the other countries that traded to the Elbe.

STA'DIUM, the course set apart for foot-races and all the other games excepting horse-racing, which were wont to be celebrated at Olympia and other places in Greece; the horse and chariot races being held in the *hippodrome* (q.v.). The stadium was of the

same form as the hippodrome, and the arrangement of the spectators was similar. The distance between the starting point and the goal was, in the Olympic stadium, about 600 Greek feet, and the stadia of other places adopted the dimensions of that at Olympia. This distance of 600 Greek feet was adopted as the chief Greek measure of length, and called a *stadium*. It was equivalent to 625 Roman feet, or 125 Roman paces; hence the Roman mile of 1000 paces, contained exactly 8 stadia.

STADTHOLDER (Ger. *stadthalter*, Dutch *stadhouder*, lieutenant or governor of a province). In the German cantons of Switzerland, the name is given to the second civil officer, who ranks next to the landamman. In the republic of the Seven United Provinces, the chief magistrate or president of the union was called the stadhouder. In the 16th c., when the tyranny of Ferdinand, duke of Alva, governor under Philip II., drove the principal towns into revolt, they chose William, prince of Orange, for their governor, and with the view of letting it be understood that the revolt was not against Philip, but against Alva, they conferred on William no higher title than that of stadhouder. On the assassination* of William in 1584, the provinces of Holland, Zeeland, and Utrecht agreeing to have one stadhouder appointed Maurice of Nassau to that office, which came tacitly to be looked on as hereditary. The stadhouderate thus instituted was considered to be at an end or in abeyance on the extinction of the line of William I., by the death of William III. However, on the triumph of the Orange party over the Republican in 1747, William IV., descended from a collateral branch of the house of Nassau, was proclaimed stadhouder, captain-general, and admiral-in-chief of the Seven United Provinces, those dignities being made hereditary in his family. His son, William V., the seventh stadhouder, was driven from his country by the French in 1795, and resigned his office in 1802; since which time the stadhouderate has never been revived, the Netherlands having, at the congress of Vienna, been formed into a kingdom.

STAËL-HOLSTEIN, ANNE LOUISE GERMAINE NECKER, Baronne de, was born at Paris, April 22, 1766. Her father was the celebrated M. Necker (q.v.) finance minister of Louis XVI., in the times immediately preceding the Revolution. Her mother was a woman of severe character, and from her earliest years subjected her to a discipline almost puritanic in its rigor. The daughter, in consequence, had no very warm attachment for her, but for M. Necker, who softened as he could by his indulgent tenderness the harsh rule of his spouse, she entertained the most ardent affection, regarding him then and always with what was almost an idolatry of fondness and admiration. Her talents were precociously developed, and while yet the merest girl, she would listen with eager and intelligent interest to the conversation of the Parisian *savans* who used to frequent the house of her father. In 1786, she was married to the baron de Staël-Holstein, Swedish minister at Paris, an elderly gentleman, with whom her happiness was probably not great, inasmuch as a few years after, a separation between them took place, two sons and a daughter having been meantime the fruit of their union. In 1788, she issued her first work, *Lettres sur les Ecrits et le Caractère de J. J. Rousseau*, which are rather a passionate eulogy of a girlish idol than a just and discriminating criticism.

Her sympathy with the revolution in its earlier stage of promise was profound, but gave place, as its later enormities were developed, to a reaction of horror, which is vividly set forth in her subsequent *Considérations sur la Révolution Française*. Her grief was extreme on the failure of the attempt to escape on the part of the royal family, and she engaged in a secret scheme for securing them a flight to England. This, however, came to nothing, and she then, along with her father, betook herself to Switzerland, his native country. The news of the king's execution inexpressibly shocked her, and she sought to save the life of the queen by publishing *Réflexions sur le Procès de la Reine, par Une Femme*, which, however, was too late to be effective. In 1795 she published at Lausanne, under the title *Recueil de Morceaux Détachés*, a collection of her juvenile writings; and the year after a treatise *De l'Influence des Passions sur le Bonheur des Individus et des Nations*, a work full of originality and genius. In 1797, order having been re-established under the directory, she was once more in Paris. From the first she distrusted the designs of Napoleon, and her *salon* became the headquarters of the anti-Bonapartist faction. In vain she was offered restitution of two million livres since 1788 due to her father from the royal treasury; she scornfully declined the bribe; and as neither fear nor favor could lead her to disguise her hostility to him, it seemed well for Napoleon to rid himself of her. She was forbidden to live in Paris, and subsequently (1802) exiled from France itself. Meanwhile, she had greatly increased her reputation by the publication of her romance of *Delphine*, and a work, *Sur la Littérature Considérée dans ses Rapports avec l'Etat Moral et Politique des Nations*. She now, for two years, traveled in Italy and in Germany, making at Weimar the acquaintance of Goethe, Schiller, Herder, Wieland, etc. The death of her father in 1804 recalled her to Coppet, in Switzerland. Subsequently she was permitted to return to Paris, and there, in 1807, she published her famous *Corinne, ou l'Italie*, the success of which was instant and immense, and won for her a really European reputation. As a bitter in the sweet of fame, however, fresh difficulties with Napoleon occurred, and she was banished anew to Coppet. Her son, the baron Auguste, then 17 years old, sought to intercede for his mother in a personal interview granted him by the emperor, whose inexorable deliverance on the occasion is too characteristic and amusing to be omitted: "Avec l'exaltation de sa tête,

la manie qu'elle a d'écrire *sur tout et à propos de rien* elle pouvait se faire des prosélytes; j'ai dû y veiller." And in candor it is to be admitted, despite of the shrieks which have ever since been put forth about Napoleon's so-called "ungenerous persecution," that he acted on the dictate of a sound prudential policy. A woman who would keep no terms with him, who was uncompromising and fearless, and an influence by the weight of her genius and reputation, was clearly in Paris, of all places, a phenomenon not to be tolerated by the head of a government such as his, more or less the sport of the hour, as always in its basis precarious. After this, when disgusted with Coppet, where she found herself subjected to a petty surveillance, Mme. de Staël rushed restlessly over Europe to Vienna, Moscow, St. Petersburg, thence through Finland to Stockholm, and afterward to London; where, in 1813, she published her great book, *De l'Allemagne*, which had previously been suppressed in Paris. As the first decisive revelation of the genius of Germany to the French people—somewhat as the earlier writings of Mr. Carlyle revealed it to the reading public of Britain, this may perhaps rank as the most important and influential of her works. Of her various experiences of travel, an interesting record is preserved in her *Dix Année d'Exil*. At the restoration she returned to her beloved Paris; from Louis XVIII. she met with a most gracious reception; and restitution was granted her of the two millions on her father's account before mentioned. Soon after her health failed; she sought its restoration in a visit to Italy in 1816, but without effect, and on July 14, 1817, she died at Paris. She was buried at Coppet; and by her will the fact was revealed that in 1812 she had privately married M. de Rocca, a French officer of hussars, aged 25, which may be looked upon as something of an escapade for a mature matron of 46. In this wedlock she gave birth to a son. M. de Rocca survived her only a few months. On the whole she had scantily been happy, as cursed with the "desires infinite and hopes impossible" which make life little better than a sad unfulfilled longing to many of her peculiar temperament and genius. Her touching wail of "Jamais, jamais, je ne serai jamais aimée comme j'aime" was a cry out of her inmost heart. In this light there may perhaps, seem some element of pathos in this marriage, which looks otherwise a little ridiculous.

Mme. de Staël—all just deduction from her claims being made—must be ranked in the first class of female genius. Without question of her real power and originality, in the combination she presents of such a force of intellect as women have but rarely exhibited, with depth and tenderness of sentiment seeking its natural outlet in a rich and impassioned rhetoric, she may curtly, yet with clearness sufficient, be defined as a sort of Rousseau in petticoats.

Her son published an edition of her works in 18 vols. in 1821, with a biographical notice by Mme. Necker de Saussure. See Norris, *Life and Times of Madame de Staël* (1853).

STAFF, in music, the name given to the five parallel lines and four intermediate spaces on which the characters indicating musical sounds are placed, the degrees of the staff indicating differences of pitch.

STAFF, in a military sense, consists of a body of skilled officers, whose duty it is to combine and give vitality to the movements and mechanical action of the several regiments and drilled bodies composing the force. The distinction between an officer on the staff of an army and a regimental officer is that the latter is concerned with his own regiment alone, while the former deals with his army, or section of an army exceeding a regiment, and regulates the combined action of the several arms and bodies of men. A good staff is all-important to the success of a military enterprise.

The *General Staff* of an army comprises the general in actual command, with the subordinate generals commanding the several divisions and brigades: as assistants to these, the officers of the adjt.-general's department—i.e., the adjt.-general, his deputy, assistants, and deputy-assistants, if the army be large enough to require all. Similarly, the officers of the quartermaster-general's department; the brigade-major; the provost-marshal; and the judge-advocate; and the controller (at the head of the civil departments); the functions of all of whom are described under their respective heads. The head of the general staff of the British army is at present a field-marshal commanding-in-chief, whose head-quarters are at the war office, of which department he is an *ex officio* member. He is responsible for the discipline of the army, and is assisted by the general officers in command of the military districts in England and Scotland, the semi-independent commander-in-chief in Ireland, and the commanders-in-chief in the various foreign possessions and colonies. India forms a nearly independent command, under a commander-in-chief, whose head-quarters are in Bengal. There are subordinate commanders-in-chief in Bombay and Madras; and in each presidency there are several military divisions. A certain period of military service, and certain qualifications, are required in an officer before he can be appointed to the general staff, and a proportion of the posts is given to officers who have passed the staff college. The fact of having passed through it, however, is not held to constitute any claim to a staff appointment.

The *Personal Staff* consists of the aids-de-camp and military secretaries to the respective general officers. These officers are appointed, within certain limits, by the generals whom they serve.

The *Garrison Staff* consists of the officers governing in fortresses and garrisons; as

commandants (q.v.), fort-majors (q.v.), town-adjutants (q.v.), fort-adjutants (q.v.), and garrison-adjutants.

The *Civil or Departmental Staff* includes those non-combatants officers who have to provide for the daily requirements of the troops. These are the commissaries for supplies and stores, chaplains, medical and veterinary departments. These departments are described under their several names.

The *Recruiting Staff* consists of an inspector-general (at the war office), and of the officers of the several brigade depots. The *Pensioner Staff* includes only the staff-officers of the enrolled force. The *Regimental Staff* includes the col., lieutenant-col., adjutant paymaster, quartermaster, inspector of musketry, and medical officers. See RECRUITING, REGIMENT.

In the French and most continental armies, the staff is divided into the *état-major*, or general staff and the *intendance*, under an *intendant-général*, which comprises all the civil departments. There is a regimental staff in addition. The want of concentration of the civil departments, often felt in the British service, led to the creation, in 1869, of the control department, subsequently split into two branches, the commissariat (q.v.) and the ordnance store departments. See INTENDANT.

In the navy, the staff of a fleet consists of the flag-officers (q.v.), the flag-lieutenants (q.v.), and secretaries; also of the inspector-general of hospitals (see MEDICAL DEPARTMENT, NAVY), and an inspector of machinery.

STAFFA, a celebrated islet on the west of Scotland, lies about 7 m. off the w. coast of Mull. It forms an uneven tableland, rising at its highest to 144 ft. above the water, $1\frac{1}{2}$ m. in circumference, and oval in shape. In the north-east, in the lee of the prevailing winds, is a tract of low shore, stretching out in beaches, and forming a landing-place. The other parts of the coast are girt with cliffs of from 84 to 112 ft. high. Regarded in sections, the rocks show themselves to be of three kinds—conglomerated tufa forming the basement; columnar basalt, arranged in colonnades, which form the façades and the walls of the chief caves; and amorphous basalt, overlying the columnar basalt, but pierced here and there by the ends of columns and by angular blocks. The most remarkable feature of the island is Fingal's or the Great Cave, the entrance to which is formed by columnar ranges on each side, supporting a lofty arch. The entrance is 33 ft. wide, and 65 ft. high, and the length of the cave is 212 feet. The floor of this marvelous chamber is the sea, which throws up flashing and many-colored lights against the pendant columns, whitened with calcareous stalagmite, which form the roof, and against the pillared walls of the cave.

STAFF COLLEGE, is an English institution founded in 1858, about two m. from Sandhurst, for the purpose of giving higher instruction to 30 (increased in 1870 to 40) officers aspiring to appointments on the staff. It thus took the place, though more effectively, of the old senior class at the royal military college. To be entitled to compete for entrance, an officer must have been five years in active service, must have passed the qualifying examination for a captaincy, and must have the recommendation of his commanding officer. A very serious examination decides which among the competitors shall be admitted to the college, one only being eligible from any battalion. While at college, the students receive their regimental pay, and the whole educational charges (about £8000 annually) are borne by the public. The course lasts two years. At the end of each year, there is an examination, not competitive. After passing the staff college, the officer is attached for duty, for a short period, to each of the arms with which he may not have already served. He then becomes eligible for appointment to the staff as opportunity may occur.

STAFF CORPS. During the wars of Wellington, the generals and staff officers were aided by a staff corps composed of intelligent officers and men who performed camp duties, made reconnaissances, and executed other necessary labors for which regimental officers or soldiers were unsuited. This corps died out after the peace. After the Crimean war, there were three staff corps—the commissariat staff corps, army hospital corps, and military store staff corps—which consisted of artificers, laborers, and orderlies, to aid in the work of their respective departments—as butchers, wardmasters, armorers, copyists, &c. The first and last were merged in 1870 into the army service corps. S. C. is also the name given to the English officers serving on the permanent Indian establishment.

STAFFORD, a co. in central Kansas, drained by the Arkansas river in the n.w., and intersected by the Atchison, Topeka and Santa Fé railroad; 792 sq.m.; pop. '90, 8520, chiefly of American birth, with colored. It consists of level plains, fertile by the water courses. Co. seat, St. John.

STAFFORD, a co. in n.e. Virginia, having the Potomac river for its e. boundary, the Rappahannock on the s.w., drained also by Acquia creek; 245 sq.m.; pop. '90, 7362, chiefly of American birth, with colored. It is intersected by the Richmond, Fredericksburg and Potomac railroad. Its surface is hilly and well timbered, lumber being the principal source of revenue. The soil is moderately fertile and richer near the Potomac river. Gold is found, and granite and freestone are quarried for building pur-

poses. Live stock is raised; other agricultural products are grain, tobacco, and wool. Co. seat, Stafford.

STAFFORD, an inland co. of England, bounded on the w. and n.w. by Shropshire and Cheshire, has an area of 732,434 acres, and a pop., '91, 1,083,273. The most elevated portion of the county is the n. where wild moorlands in long ridges, separated by deeply cut valleys, extend from n.w. to s.e., and subside as they near the valley of the Trent. The surface is low and undulating in the midland regions, but becomes hilly again in the south. New red sandstone occupies the whole of the central parts; the Pottery coal-field occupies the n., and the Dudley coal-field, remarkable also for its abundant and rich iron ores, occupies the south. The Trent, flowing first s.w. through the county, then n.e. along its eastern border, is the chief river. The climate is cold and humid, much of the soil is clayey, and agriculture is in a backward condition. Its manufactures, however, are extensive and varied, including cutlery and iron-ware, pottery, shoes, glass, and cotton, silk and leather goods. The county of Stafford returns seven members to the house of commons.

STAFFORD, the co. t. of Staffordshire, stands on the Sow, 29 m. n.n.w. of Birmingham. The usual municipal institutions of county towns are the chief buildings, and there are two fine and partly ancient parochial churches. Tanning, cutlery, and the manufacture of shoes are the chief branches of industry. Stafford sends one member to the house of commons. Pop. '91, 20,270.

STAFFORD, HENRY, Duke of Buckingham, 1440-83; b. England; assumed the title in 1460. He was one of the most powerful of the adherents of the duke of Gloucester, afterward Richard III., while the latter, then protector, was conspiring to seize the throne. He assisted Richard in his efforts against earl Rivers and lord Gray, which resulted in the destruction of those noblemen; and received as a reward for his services the office of chief-justice and constable of the royal castles in Wales, and later that of lord high constable of England. But he afterward joined the Lancastrians, and being betrayed to Richard, was captured, attainted, and suffered death on the scaffold at Salisbury, Nov. 1, 1483.

STAFFORD, WILLIAM HOWARD, Viscount, 1612-80; b. England, and educated as a Roman Catholic. In 1634 married a sister of the 13th baron Stafford, and on the latter's death, being then sir William Stafford, assumed his title. His claim to this through his wife was afterward disputed, but finally decided in his favor, and a new creation was made by the king, declaring him baron and afterward viscount Stafford. The civil war found Stafford a firm adherent of the king, but he changed his course so far after the restoration as to frequently oppose the royal will from his place in the house of peers. In 1678 Stafford was one of those denounced by the infamous Titus Oates as a conspirator in the pretended popish plot. He was accordingly arrested, with four other noblemen similarly accused, and committed to the Tower. He was impeached on a charge of high treason, Dec., 1678, and in the following November the impeachment trial began before the house of lords under the presidency of sir Heneage Finch, afterward the earl of Nottingham. Despite a spirited defense against suborned testimony, Stafford was found guilty. He was publicly executed on Tower hill, Dec. 29, 1680, to the last protesting his innocence of act or intent to conspire against his sovereign. King James created his widow a countess in her own right; and James II. made his eldest son earl of Stafford in 1688, a title which lapsed in 1762. In 1824 the act of attainder was reversed by parliament, and the following year sir George William Jennings, bart., was recognized as baron Stafford.

STAG, a name familiarly given to a person who applies for an allocation of shares in a joint-stock concern, with a view of selling the allocation letter to another party for a small consideration. When no such consideration or premium is obtainable, the *stag* does not pay the deposit, which by his application he had become bound to do, and relinquishes any further interest in the undertaking. Persons acting thus, however, are liable to prosecution and exposure as defaulters. During the great railway mania of 1846 the stock market was thronged with stags.

STAG, or RED DEER, *Cervus elephas*, a species of deer (q.v.) with round antlers, which have a snag at the base in front. The female has no horns, and is called a *hind*. The young male during the first year acquires mere knobs in place of horns. In the second year they are longer and pointed, when the animal is called a *brocket*. The branching of the horns increases every year till the sixth, when the name *hart* (q.v.) begins to be applied. After this the age is no longer indicated by an increased number of branches, but the antlers become larger and thicker, their furrows deeper, and the *butt* at the base more projecting. The oldest stags have seldom more than 10 or 12 branches, although an instance has occurred of 33 on each antler. A fine stag is 4 ft. or more in height at the shoulder. The color is reddish brown in summer, the rump pale; in winter it is brownish gray. The female is smaller than the male. The young is at first spotted with white. The stag is a native of Europe and the north of Asia. It was anciently common in all parts of Britain, but is now almost extinct except in the Highlands of Scotland, where large herds still exist, particularly on the Grampians, and the sport of deer-stalking is pursued, in which the rifle is now generally used; although in former times the stag was hunted, hounds of a peculiar breed called staghounds (q.v.) being employed for the purpose. The forest laws of England were extremely strict for

the preservation of this noble game, the unauthorized killing of a stag being even a more unpardonable offense than the killing of a man. The stag feeds on the buds and young shoots of trees and on grass, or in the severe weather of winter on bark and mosses. The speed of the stag is very great. It has also great powers of swimming, and has been known to swim 10 miles. When hard pressed by hunters it turns to bay, and is not approached without danger. At the pairing season, which is in August, even tame stags become so excited that it is not safe to approach them. The domestication of the stag is never very complete. In fighting the stag uses not only its horns, but its fore-feet, with which it gives severe blows to an adversary. The flesh of the stag is not so good as that of the fallow deer.—Among the species of deer most nearly allied to the stag are the wapiti (q.v.), an American species, and several species belonging to the warmer parts of Asia and the north of Africa. They all have round branched antlers, with a basal snag in front, and a tuft of hair on the hind legs above the middle of the metatarsus.

STAG BEETLE, *Lucanus*, a genus of coleopterous insects, of the family *lamelli-cornes*, remarkable for the large projecting mandibles of the males, which have large denticulations, and somewhat resemble stags' horns. The antennæ terminate in a club composed of many leaflets, disposed on an axis like the teeth of a comb. The **COMMON STAG BEETLE** (*L. cervus*) is one of the largest of British insects, the males being fully two in. long. It flies about in the evening in the middle of summer, chiefly frequenting oak woods. The larva feeds on the wood of the oak and willow, and is injurious to the trunks of trees, into which it eats its way very rapidly. It is supposed to be the *cossus* of the ancient Romans, much esteemed by them as a delicacy. It lives for several years before undergoing its transformations. In its perfect state, the stag beetle is a formidable-looking insect, and its powerful mandibles are capable of inflicting a pretty severe bite, if it is incautiously seized, but it is not venomous. Some of the tropical stag beetles are remarkable for their brilliancy of color.

STAGE. See THEATER.

STAGER, ANSON, 1825-85; b. Ontario co., N. Y.; d. Chicago; engaged in printing when a boy, but early became interested in the building of telegraphs. Under the direction of Henry O'Reilly, he held an office at Lancaster, Penn., 1846, where he was the first to economize batteries by charging many wires at the same time from the same source. He was also the originator of the system of connecting long lines of telegraphs, thus saving the risk attached to the frequent repetitions of messages. He was the first general supt. of the New York and Missouri valley telegraph co., connecting Buffalo, N. Y., with Louisville, Ky. Upon the organization of the Western Union co., he became its general supt.; was the originator of the present elaborate and excellent system of railroad telegraphs in the w. and n. w. During the civil war, he had charge of the telegraph wires in O., Ind., and Ill.; organized and had control of the military telegraph at Washington; was appointed chief of the U. S. military telegraph throughout the country, 1861. He was also placed in charge of the cipher correspondence, and invented a system of cryptography which completely baffled the confederate telegraphers. He was breveted brig.-gen. for his meritorious and distinguished services. He afterward resided at Cleveland and Chicago, in charge of the central division of the Western Union co. He was prominently connected with the electric light manufacture, and with the development of the telephone interests in Chicago.

STAGGERS is a popular term applied to several diseases of horses. Mad or sleepy staggers is inflammation of the brain, a rare but fatal complaint, marked by high fever, a staggering gait, violent convulsive struggling, usually terminating in stupor; and treated by bleeding, full doses of physic, and cold applied to the head. Grass or stomach staggers is acute indigestion, usually occasioned by overloading the stomach and bowels with tough hard grass, vetches, or clover, a full meal of wheat, or other indigestible food. It is most common in summer and autumn, is indicated by impaired appetite, distended abdomen, dull aspect, unsteady gait; and is remedied by full doses of purgative medicine, such as six drams of aloes and a dram of calomel rubbed down together, and given in a quart of thin well-boiled gruel. Frequent clysters, with hand-rubbing and hot water to the belly, are likewise useful. Where the dullness increases, stimulants should be freely given. See HYDATID.

STAGHOUND, a large and powerful kind of hound (q.v.), formerly much used in England for hunting the stag, but now almost extinct. It is supposed to be a breed of the old English southern hound. In scent, it is almost equal to the bloodhound; in fleetness, it is inferior to the foxhound. It has great power of endurance, and has been known to run 50 m. after a stag. It is also courageous, and does not hesitate to attack the stag when at bay.

STAGIRA (ancient name for Stavros), a t. in s.e. Macedonia, on the gulf of Contessa, otherwise called the gulf of Orphano, the *Sinus Strymonicus* of the ancients. According to Thucydides it was founded by a colony from Andros, and is situated on the upper shore of the peninsula of mount Athos, near its junction with the main-land. It is in the district of Chalcidice, and is celebrated as the birthplace of Aristotle. It declined during the Peloponnesian war. The surrounding country is noted for its fertility, producing corn, wine, oil, and fruit.

STAHEL, JULIUS, b. Hungary, 1825. He served in the Austrian army, but joined the Hungarian patriots, and was an *aide* to Görgei. After the failure of the movement, he visited Germany and England, and finally came to New York and became a journalist. He was brig.-gen. of vols., 1861, and commanded a division under Sigel. In 1866 and 1877 he was U.S. consul at Yokohama, Japan.

STAHL, FRIEDRICH JULIUS, 1802-61; b. Munich; prof. of law at Erlangen, Wurzburg, and Berlin. He served successively in the Prussian chamber of deputies, the Erfurt parliament, and the upper house of the Prussian legislature. He was a prominent member of the Lutheran party, and one of the founders of the German church diet. In his chief work, *Philosophie des Rechts*, he advocates a "Christian state," which shall support the church by the secular arm.

STAHL, GEORG ERNST, a celebrated German physician and chemist, was born at Anspach, October 21, 1660, studied medicine at Jena, and after practicing successfully for some time, was called, in 1694, to the chair of medicine, anatomy, and chemistry, in the newly-founded university of Halle; whence he removed to Berlin in 1716, where he was appointed physician to the king of Prussia. He was a member of the Berlin Academy, and died in that city May 14, 1734. According to Blumenbach, Stahl is to be considered as one of the greatest and most profound physicians the world has ever seen, though the mysticism with which his works are imbued is to be reprehended. Stahl's system of medicine, which combined the physiology of Van Helmont (see HELMONT, VAN) with the psychology of Descartes, is founded on the supposition of the existence of a mysterious force residing in, but independent of, and superior to matter; this force, the *anima* (or "soul"), not only forms the body, but directs it in the exercise of all its functions, and this, too, sometimes unconsciously; though the way in which this influence is exercised he does not explain. Being subject to error by nature, the "anima," by negligence or maladroitness, originates diseases in the body, which it then attempts to cure, through the functional action of the various parts. Stahl held that art ought only to commence where nature had ended, and to be useful, it should follow a similar course of action; he was also of opinion that plethora, either local or general, was one of the chief causes of disease. His system of therapeutics corresponded with his pathological principles, and was confined mostly to bleeding and the use of mild laxatives. His psychological theory of the connection between the soul and body led him into a discussion with Leibnitz (who had falsely charged him with propounding materialism), from which he emerged victorious on the essential points of their respective theories; though Leibnitz had the advantage in matters of detail. Subsequent physiologists have made Stahl's opinions the object of ridicule, though his doctrine of the "anima" is, under the name of "vital principle" and "nature," generally adopted at the present day; but his supercilious contempt for chemistry as a medical agent has long ceased to be generally upheld. Nevertheless, Stahl was one of the ablest chemists of his time, destroyed, in his usual trenchant style, numberless absurd opinions which had found their way into the science, and propounded the first theory of combustion (see PHLOGISTON), which was universally accepted till the time of Lavoisier (q.v.). His works, according to Haller, number 250, but the chief are—*Theoria Medica vera* (Halle, 1707, 1708, 1737), which contains his medical theory, and *Zymotechnia Fundamentalis, seu Fermentationis Theoria Generalis* (Halle, 1697), in which his chemical opinions are set forth. An account of his opinions is found in Haller's *Bibliotheca Medicinæ Practicæ*, vol. iii.; Sprengel's *Histoire de la Médecine*; A. Lemoine's *le Vitalisme et l'Animisme de Stahl* (Paris, 1864), and numerous other works.

STAIGG, RICHARD M., b. England, in 1817; came to this country while young and worked as a mechanic in Newport, R. I., where he had the *entrée* of the studios of Jane Stuart and Alston, and beginning there the study of miniature painting, rose rapidly to eminence in that profession. He painted the portraits of Allston, Everett, and Webster, the latter now preserved in the rooms of the Historical society in Boston. His genre pictures and coast scenes are especially prized; among them "News from the War," "The Crossing Sweeper," and "The Love Letter." He d. 1881.

STAINED GLASS. See GLASS.

STAINER, Sir JOHN, b. England, 1840; studied music at Oxford, where he was organist of Magdalen college and of the university church. He became organist of St. Paul's, London, 1872-1888. He published his *Theory of Harmony* in 1871. He is a fine instrumentalist, and has composed many anthems and songs. He was knighted in 1888 and in 1889 was prof. of music at Oxford university.

STAINS FOR WOOD. A variety of stains have recently been invented for the purpose of giving to the cheaper kinds of wood, such as deal, etc., the appearance of the more costly kinds. These are chiefly solutions of certain metallic salts, combined with vegetable infusions.

STAIR, LORD. See DALRYMPLE FAMILY.

STAIRCASE. This feature, now so important in all houses, was of small note till about the time of queen Elizabeth. Previously, stairs were all constructed on the circular pian, revolving round a central axis or newel, and were called turret or corkscrew stairs. During the 16th and 17th centuries, staircases with wide straight flights were

first introduced, and were made leading features in the mansions of the Elizabethan style. They had usually massive oak balusters with carved pedestals, and were ornamented with carved panels, pendants, etc.

STAKE NETS. See **SALMON**.

STALACTITES AND **STALAGMITES** are found in caves and other places where water charged with carbonate of lime is subject to evaporation. Water impregnated with carbonic acid is able to dissolve lime, and as all rain and surface water contains more or less carbonic acid, it takes up in its passage through the earth to the roofs of caves a certain amount of lime. When the water is exposed on the roof or floor of the cave, evaporation takes place, and so both the bulk of the water and its solvent power are reduced, and a thin pellicle of solid carbonate of lime is deposited. When this takes place on the roof of the cave, long icicle-like pendants are formed, which are called stalactites; and when the water drops upon the floor, a stalagmitic layer is formed, which rises at the points where the largest supply of material exists, in the form of pillars to meet the overhanging stalactites. In some caves, the descending and ascending points have met and formed a series of natural columns as if supporting the roof. The amount of the deposition is very great in some caves, and the wonderful variety and singular groupings of the stalactites give them a peculiar beauty. The caves most remarkable in this way are the cave of Adelsberg in Styria, the grotto of Antiparos in the Grecian Archipelago, Mammoth Cave in the United States, and the caves of the peak in Derbyshire.

STALIMNE. See **LEMNOS**.

STALWARTS, a term belonging to the vocabulary of American politics, and first generally used in the spring of 1881. In that year, President Garfield, setting aside the usual precedent, appointed Mr. W. H. Robertson Collector of the port of New York, without consulting the New York senators, and in opposition to their known preferences. The senators in question, Messrs. Roscoe Conkling and Thomas C. Platt, believing this act to have been inspired by Mr. Blaine, then secretary of state, who was personally unfriendly to Mr. Conkling, and regarding it as a direct blow at their influence in the state, resigned from the Senate. Their friends in the New York legislature at once sought to have them re-elected as a "vindication"—an attempt that was vigorously opposed by the partisans of the administration. A long and intensely bitter fight ensued. Those who tried to re-elect Messrs. Conkling and Platt, received the name of Stalwarts, while their opponents were dubbed "Half Breeds" (q.v.), the latter name implying that they were not thoroughly imbued with the party traditions. The immediate result of the contest was the triumph of the Half Breeds who secured the election of Elbridge G. Lapham and Warner Miller in the place of Messrs. Platt and Conkling. The indirect results were momentous and far-reaching. To the bitterness engendered by the contest was due the assassination of President Garfield by the miserable Guiteau; while the division in the party led to the election of Grover Cleveland as democratic governor of the state in the following year by a majority of some 200,000 votes—the largest ever given to a gubernatorial candidate, and one which at once made Mr. Cleveland an aspirant for the presidency. To the defection of the Stalwarts in New York in 1884, Mr. Blaine's loss of that state at the presidential election is attributed by many. The term Stalwart at the present time receives a somewhat wider application than formerly. It is now used of any strict partisan, and is thus a term antithetical to Mugwump (q.v.). See **PARTY NAMES**.

STALYBRIDGE, a market-t. and parliamentary and municipal borough, partly in Lancashire and partly in Cheshire, stands on the Tame, eight m. e. of Manchester. It is remarkable chiefly for its cotton manufactures. The print-works, iron-foundries, and machine-shops are also numerous and important. Free communication by railway is afforded in every direction. Pop. '91, 26,783.

STAMBOUL. See **CONSTANTINOPLE**.

STAMBULOFF, STEPHEN. A Bulgarian statesman, born in 1853. In the Russo-Turkish war of 1877-78, he served in the Russian army. After the election of Alexander I. as Prince of Bulgaria, he became leader of the Liberal party, and in 1884 president of the Sobranye. His opposition to the projects of Russia was always marked, and as chief minister under Alexander's successor, Ferdinand, he carried out his policy with such energy as to be styled "the Bismarck of Bulgaria." So autocratic, however, did he become as to offend both Prince and people, and in May, 1894, he resigned office. On July 18, 1895, he was assassinated in the streets of Sofia. See the life, by Beaman (1895).

STAMENS are those parts in the flowers of phanerogamous plants which excite the pistil to the formation of the fruit, and thus effect fertilization or fecundation (q.v.). A stamen consists of a receptacle—the *anther*; which contains a dust—the *pollen*—various in color, but generally yellow, and is generally supported on a stalk called the *filament*; the anther being the blade of a metamorphosed leaf, and the filament the leaf-stalk. The filament is, however, sometimes wanting, and the anther is then said to be *sessile*. Each anther generally consists of two cells, forming two lobes, which, before they open to give forth the pollen, are again divided into two

cell-like parts, and at the time of their maturity open by longitudinal clefts, by pores, or by valves, to scatter the pollen, which is conveyed to the stigma either by its own falling, by the wind, or by the insects which seek honey in flowers. See **PISTIL**. The pollen consists of single cells, which are usually free; more rarely, the pollen of each cell is united into a mass, called the *pollen-mass* or *pollinium*, as in the *Orchidæ* and *Asclepiadaceæ*. The stamens are either found along with the pistil in the same flower, and are then arranged around it, in which case the flower is *hermaphrodite*, or they are placed by themselves in separate flowers, which are therefore called *male* flowers. The stamens are sometimes united together, generally by the filaments, which form a tube, and the flower is *monadelphous*; sometimes, by their union, they form two sets, when the flower is *diadelphous*; sometimes three or more, when it is *polyadelphous*; and the filaments are sometimes united with the pistil into a column, from which the anthers spring, as if they grew from the pistil, when the flower is *gynandrous*. See **BOTANY**. The stamens form either one or more whorls, and when in one whorl are either opposite to the petals or alternate with them. The latter is regarded as their normal position. Sometimes, by abortion, there is only one stamen. Being leaf-organs, stamens arise from the axis; but they very frequently grow upon the corolla, so that they seem to derive their origin from it. When the stamens seem to arise from the corolla or from the calyx, they, and also the flower, are said to be *perigynous* (Gr. *peri*, around, and *gyne*, a wife); when they grow from the pistil, they are *epigynous* (Gr. *epi*, upon); and when from beneath it, *hypogynous* (Gr. *hypo*, under). These distinctions have been much made use of, by Jussieu and others, in classification. The transitions of petals into stamens can be easily traced in some flowers, for example, in the water lily. In double flowers, the stamens have been changed into petals. Linnaeus adopted the stamens as the means of his division of plants into classes (see **BOTANY**); but in so far as the classification was founded on their mere number, it was artificial, the number of stamens being various in plants very closely allied. Stamens are among the organs of plants which most frequently display irritability (q. v.). See *illus.*, **BOTANY**, vol. II.

STAMFORD, a town and city in Fairfield co., Conn.; on Long Island sound, and the New York, New Haven, and Hartford railroad; 34 m. e. of New York. The town was settled in 1640, under the jurisdiction of the colony of New Haven; was named in 1642; and subjected itself to the jurisdiction of Connecticut in 1662. The city, comprising four-fifths of the population of the town, was set apart and given a city charter in 1893. It contains a hospital, the Ferguson library, numerous small parks, the town hall, an imposing high school building, electric light and street railroad plants, waterworks supplied from Trinity lake 18 miles distant, and several national and savings banks. The principal manufactures are dye stuffs, iron castings, machinery, shoes, locks, pottery, pianos, billiard tables, drugs, carriages, thread, hats, and pumps. Pop. '90, 15,700.

STAMFORD, an ancient market-t. and a parliamentary and municipal borough of Lincoln, on the Welland, which is navigable hence to the sea, 11 m. n.w. of Peterborough. Agriculture is almost the exclusive pursuit of the inhabitants of the district around, and Stamford is chiefly remarkable for its ancient remains. It first appears in history in 449, when the Britons and Saxons here defeated the Picts and Scots.

STAMMERING AND DEFECTIVE SPEECH. Stammering is an affection of the vocal and enunciative organs, causing a hesitancy and difficulty of utterance, and respecting the nature and the origin of which a variety of different opinions has been entertained. Stammerers themselves often attribute the varying conditions of their impediment to causes which must be purely imaginary, such as the state of the wind, the changes of the moon, etc. There can be no doubt that the impediment is aggravated by depression of spirits, derangement of the digestive organs, physical debility, etc.; but these influences have nothing to do with the primary cause of the infirmity. A nervous dread of speaking is usually associated with stammering; but this is rather the result than the cause of the impediment. If constitutional nervousness were productive of stammering, the number of sufferers would be vastly greater, and it would include a larger proportion of females than of males; whereas the robust sex furnishes by far the greater number of cases; and it is noticeable, besides, that stammerers are not in general persons of weak nerves, otherwise than in connection with the act of speaking. Any physical defect will render a person nervous when the peculiarity is made a subject of observation, and it is in this way only that nervousness is associated with speech in cases of stammering. The strength of this impediment lies in *habit*, in mismanagement of the breath and the organs of utterance, rendered habitual before the development of reason and observation; and the removal of the defect depends on the acquirement of voluntary control over the mechanical agents of speech. The nervousness which unfits the stammerer for self direction gradually subsides as his will attains a mastery over the processes of speech; and perseverance in a discipline of systematic and guarded utterance rarely fails to remove the impediment, and the fear which accompanied it.

The first manifestations of stammering usually take place during the weakness attendant on disease, or after a fall or sudden fright; but sometimes the impediment appears to arise from imitation, and children have been known to be infected by even the most casual example. Thus, when one member or visitor of a family stammers, the younger members of a family are very apt to be similarly affected. From this cause defects of speech run so much in families, that many persons have thought them to be hereditarily transmitted. This, however, is altogether a mistake.

Stammering generally begins about the fourth or fifth year of age; but harshness in checking children, or impatience in connection with messages or lessons, may induce the impediment at a considerable later period. Boys of ten or eleven years of age have been excited into the habit by injudicious hurry and peremptoriness at school. The little stammerer, when he cannot be more directly assisted, should be kindly counseled to take time and speak slowly, and he should by no means be ridiculed or reproved for what he cannot help, and is not taught how to avoid.

The varieties of stammering are so great, that scarcely two cases are found precisely alike. In some there is but little outward manifestation of effort; in others, the futile attempts are painfully demonstrative. The silent straining to speak causes the eyeballs to protrude, and the veins of the face and neck to swell, till relief from apparent choking comes in fitful, ungovernable bursts of sound. In almost all cases the head oscillates loosely on the neck, and is forced upward by the misdirected current of breath; while the larynx, the organ of sound, is from the same cause agitated in continual efforts to ascend, and the voice is consequently abrupt and intermittent, and unnaturally acute. The muscles of the face participate in the general upward action, and sometimes the spasmodic contortions extend over the whole body, causing the stammerer to rock in his chair, or start wildly to his feet. These muscular disturbances arise simply from disordered respiration, and they disappear when the habit of closing the glottis and compressing the organs of articulation is overcome, and the air is allowed to pass freely in or out of the lungs.

The terms stuttering and stammering are often used synonymously, but the former term is properly, or, at least, conveniently, limited to a loose and imperfect action of the organs of articulation, as distinguished from the irregularity of breathing and the convulsive and choking symptoms which invariably accompany stammering. In stuttering, the organs meet and rebound again and again in reiteration of syllables before words can be fully formed. The source of this difficulty lies mainly in the lower jaw. When this organ is brought under control, and the effort of speech is transferred from the mouth to the throat—where all voice is formed—the power of fluency is readily obtained. But stuttering is rarely unaccompanied by some degree of spasmodic stammering, and the two forms of impediment, while theoretically distinct, are generally blended in mutual aggravation.

Stammering is, in nearly every case, perfectly curable, as it seldom arises from organic defect. The means of cure must, however, often be continued for a length of time before the stammerer is free from the danger of relapse. The best time for the cure is undoubtedly the earliest, before the habit has acquired full strength, and before the sufferer has endured the most grievous mortifications and drawbacks of the impediment. But the adult stammerer generally brings to the curative task a higher appreciation of its importance, and a greater care and concentration of effort than the child is capable of; and these qualities almost compensate for the disadvantage of long-established habit. Parents often unwisely defer the attempt to correct impediments of speech, in the hope that the defects will disappear as the child gains strength and reaches riper years. But the hope is very rarely realized; and were it otherwise, the misery of years of impediment, and the hindrance to education which stammering certainly involves, are evils to be avoided by all possible means. With this, as with all habits, "prevention is better than cure;" and stammering would be easily and certainly prevented by timely advice carried out with ordinary care in the nursery.

The means that have been proposed for the cure of stammering have been as various as the theories of the nature of the defect; and sometimes the "cure" has been apparently but little better than the disease. Drawling, singing, interpolations or elisions of letters, speaking with the teeth closed, or with the tongue pressed to the roof of the mouth, sniffing, whistling between words, beating time to utterance, stamping the foot, jerking the body, forks on the tongue, pebbles in the mouth, or tubes fixed between the organs, bands compressing the larynx, and other absurd and uncouth devices, have been, under cover of expedient secrecy, practiced on unhappy stammerers. But the removal of this defect, as above shown, depends on the skillful application of scientific principles, respecting which there is no mystery save that which arises from the little attention that has been paid to the science of speech.

From the preceding account of the nature of stammering, it is almost superfluous to add that the cure of this impediment does not fall within the province of surgery. Yet the barbarous operation of cutting a wedge from the root of the tongue—introduced from Germany about 25 years ago—and the equally futile and cruel operation of excising the tonsils, have been, within no distant date, extensively practiced by surgeons in this country.

The habit of stammering can only be counteracted by the cultivation of a habit of correct speaking; and the latter can only be acquired by studying the processes of speech, the relation of breath to articulate sounds, the positions of the tongue and the other oral organs in molding the outward stream of air; and by a patient application of these principles in slow and watchful exercise. The lungs constitute a pair of bellows, and the mouth, in all its varying shapes, the nozzle of the bellows. The passage of the throat must be kept open, and the breath expelled by means of the ascent of the diaphragm, not by downward pressure of the chest. All sound originates in the throat, and all effort

in speech must be thrown back behind the articulating organs, which must be kept *passive*, yielding to the air, always opening to give it exit, and never resisting it by ascent of the tongue or of the jaw. The head must be held firmly on the neck, to give free play to the attached organs; and the great principle must never be lost sight of that *speech is breath*; and that, while distinctness depends on precision and sharpness of the oral actions, *fluency* depends on the unrestrained emission of the material of speech—the air we breathe.

Besides stammering and stuttering, there are many other forms of vicious articulation, which are rather defects than impediments of speech. The elementary sounds most subject to mispronunciation are those of *r* and *s*, giving rise to the common defects of burring and lisping. Burring consists in vibrating the uvula or the edge of the soft palate, instead of the tip of the tongue; and lisping consists in applying the tongue to the teeth or the gum, so as to intercept the breath, and force it over the sides instead of the center of the tongue. The sound of *l* also is often defective, *w*, *y*, *ng*, or a vowel being substituted for the lingual articulation. Other substitutions of one element for another are common, such as *t*, *d*, and *n*, for *k*, *g*, and *ng*; *s* or *z* for *th*; *s* for *sh*, etc. There are also defects which arise from organic malformation, and require the aid of surgery; as when fissure exists in the palate, and the breath cannot be enclosed behind the lips or tongue, but escapes into the nostrils; when the tongue is too closely tied to the bed of the mouth, and the tip cannot be raised to the palate; when the teeth are so irregular or abnormally numerous as to leave the tongue too little room to act, etc. In some cases the breath escapes into the nostrils when there is no organic cause for the peculiarity, and *r*, *l*, *s*, and other elements are nasally affected, merely from habit. The nasal passages are, in other cases, insufficiently free, and *m*, *n*, and *ng* are scarcely distinguishable from *b*, *d*, and *g*.

There are comparatively few persons who have perfect command over their vocal organs. Speaking, which is in reality an art, is exercised only as an instinct; and thus, as an eminent American author (Dr. Rush) observes, "some men only bleat, bark, whinny, or bray a little better than others." It is some consolation to those who have been compelled by defects to study the art of speech, that they exercise the crowning faculty of man's nature more worthily than others, and thus become, perhaps, better speakers than they would have been without the stimulus of defect or impediment.

Speaking, when the respiration is properly conducted, is one of the most healthful exercises; but violent or long-continued effort is injurious to the chest, when the lungs are not kept well inflated. Frequently, also, under such circumstances, the vocal chords become permanently relaxed, and total loss of voice sometimes ensues.

The acquirement of the power of speaking in infancy is dependent on the possession of hearing, so that deaf children are also mute. Under proper training, however, they may be taught to articulate, as the organs of speech are very rarely imperfect. Children who have been subject to fits or other cerebral affections, or who are deficient in imitative power, are sometimes very backward in learning to speak. In such cases, great care is requisite to direct the early attempts, and prevent the formation of bad habits. Many of the worst forms of defect and impediment owe their origin simply to the want of proper direction in the production of elementary sounds, when the little sufferers have failed to enounce them correctly by natural imitation.

It is unnecessary to enumerate the various English, American, and foreign authors who have propounded conflicting theories of the cause, and schemes for the cure of impediments of speech. Of the systems practiced in this country at the present day, those of Dr. Hunt and Mr. Melville Bell have been most fully published. The views of these authors differ but little, and are in substance the same as those contained in this article.

STAMP ACT. This act was one of those procured from the British parliament by the direct influence of George III., with that design toward oppression which characterized his course with regard to the colonies, and which finally brought about the revolution. It was passed in Mar., 1765, receiving the royal signature on the 22d of that month, and to take effect Nov. 1. Its immediate result was to bring about the assembling of a colonial congress at New York, Oct. 7, 1765; and on the day of its taking effect, bells were tolled, flags were placed at half-mast, and newspapers were put in mourning; while no officials were found courageous enough to enforce the obnoxious law. The act declared that no legal instrument should be valid in the colonies unless it bore the government stamp. On Mar. 18, 1766, it was repealed.

STÄMPFELI, JAKOB, 1820–79; b. Switzerland; studied law, and became a lawyer, and a radical journalist. He was head of the financial department in the council of state in 1846, and represented Bern in the diet in 1847, when he advocated the expulsion of the Jesuits and war with the Roman Catholic cantons. He was president in 1849, 1851, 1856, and 1862; several times vice-president, and minister of war. In 1872 he was one of the Geneva arbitrators under the treaty of Washington.

STAMPING OF METALS. There are different kinds of stamping. The plan adopted for producing coins or medals is described under **MINT**, and the preparation of the dies used, under **DIE-SINKING**. For the ordinary stamped brass-work, so extensively made

In Birmingham, a stamping-machine is employed, of which the essential parts are a *die*, a reverse or counter-die, and a *hammer*. A toothed rack, with arrangement for catching the hammer after it rebounds, is only used for special purposes. The die, which is made of cast-iron or steel, is fixed to the bottom of the stamp, and the reverse is attached to the hammer, which works between two guides. Pieces of thin rolled brass are cut to size, and one placed upon the die; the hammer, with the counter-die, is now raised to a sufficient height by a windlass and rope, or other means, and allowed to fall, and thus force the thin plate into the die. The plates from the first blow are then annealed. Repeated blows and annealings follow until the article is "brought up," slight alterations in the reverse being from time to time required. Sometimes as many as 30 blows are necessary, but 10 or 12 strokes will suffice for an object with a considerable depth of raising. Globular articles are stamped in two or more pieces, and then soldered together.

The stamping process was first adapted to the production of hollow shapes in sheet-iron by Mr. T. Griffiths in 1841; and since then, the manufacture of such goods as dish-covers, basins, and teapots has been improved and extended to a surprising extent. In the case of a dish-cover, for example, a single sheet of iron is brought to the required shape by repeated stampings and burnishings upon a chuck. It is afterward tinned with great ease, there being no joints to interfere with the operation; for the same reason, iron basins stamped out of a single sheet can be readily enameled. The old way of forming these articles by hand-labor was very tedious and clumsy.

German silver is too brittle a metal to be stamped like brass or iron, consequently it has only hitherto been made into small objects, such as spoons and forks, by this process. But the Messrs. Elkington of Birmingham are now making articles of considerable size in this material, by means of a stamping-press worked by hydraulic power. A number of graduated dies are used for one object, each pair coming gradually nearer the desired shape, but none of them making an impression deep enough to strain the metal.

For stamping-machines used in dressing metallic ores, see METALLURGY.

STAMPS, or **STAMP DUTIES**, are taxes imposed in England on all paper whereon private deeds or other instruments of almost any nature are written. It is a convenient mode of raising the public revenue, and was first instituted by a statute of 5 and 6 Will. and Mary, c. 21. The subsequent statutes are varied and complicated, and embrace nearly every kind of legal document.

STANBRIDGE, JOHN, abt. 1450-abt. 1525; b. England; made perpetual fellow of New college, Oxford, 1481. About 1486 he formed a connection with the free school adjoining Magdalen college, which lasted many years, entering as first usher and succeeding John Anwykyl as head master. He was author of the first printed school-books circulated to any extent in England; among them *The Accydence of Mayster Stanbridge's Oone Makynge*, printed in the 15th c., and *Embryon Relimatum sive Vocabularium*, 8 editions, printed by Wynkin de Worde.

STANCHIONS, or **STANCHELS**, upright iron bars fixed in the stonework to protect windows. They are sometimes let into the stone at top and bottom: sometimes at bottom only, and ornamented with fleurs-de-lis, etc., at top.

STANDARD. In its widest sense, a standard is a flag or ensign under which men are united together for some common purpose. The use of the standard as a rallying-point in battle takes us back to remote ages. The Jewish army was marshaled with the aid of standards belonging to the four tribes of Judah, Reuben, Ephraim, and Dan, and the Egyptians had ensigns with representations of their favorite animals. The flag of Persia was white, and, according to Xenophon, bore in his time a golden eagle with expanded wings; it was fixed on a chariot, and thus conveyed to the field of battle. Æschylus, in enumerating the six chiefs who, headed by Polynices, set themselves in battle array against Thebes, describes the device on the standard of each. In the earliest era of Roman history a bundle of hay or fern is said to have been used as a military standard, which was succeeded by bronze or silver figures of animals attached to a staff, of which Pliny enumerates five—the eagle, the wolf, the minotaur, the horse, and the boar. In the second consulship of Marius, 104 B.C., the other animals were laid aside, and only the eagle retained; and down to the time of the later emperors, the eagle, often with a representation of the emperor's head beneath it, continued to be carried with the legion. On the top of the staff was often a figure of Victory or Mars. Each cohort had also an ensign of its own, consisting of a serpent or dragon woven on a square piece of cloth, and elevated on a gilt staff with a cross-bar. Under the Christian emperors, the *labarum* (q.v.) was substituted for the imperial standard. Various standards of great celebrity occur in mediæval history, among which may be enumerated the *flag of the prophet* (q.v.); the standard taken from the Danes by Alfred of England; and the oriflamme, originally belonging to the abbey of St. Denis, and borne by the counts of Vexin, which eventually became the standard of the French kingdom.

In strict language, the term standard is applied exclusively to a particular kind of flag, long in proportion to its depth, tapering toward the fly, and, except when belonging to princes of the blood royal, slit at the end. Each baron, knight, or other commander in feudal times, had a recognized standard, which was distributed among his

followers. The length of the standard varied according to the rank of the bearer. A king's standard was from 8 to 9 yards in length; a duke's, 7 yards; a marquis's, $6\frac{1}{2}$ yards; an earl's, 6 yards; a viscount's, $5\frac{1}{2}$ yards; a baron's, 5 yards; a banneret's, $4\frac{1}{2}$ yards; and a knight's, 4 yards. There was never a complete coat-of-arms on the standard; it generally exhibited the crest or supporter with a device or badge of the owner, and every English standard of the Tudor era had the cross of St. George at the head. Standards were registered by the heralds, and the charges on them selected and authorized by an officer of arms.

The so-called royal standard of Great Britain is more properly a banner (q.v.), being a square flag with the national arms covering the entire field without any external accessories. The so-called cavalry standards in use in the British army are also in strictness banners. They are small in size; their color is determined by the color of the regimental facings, and they are charged with the cipher, number, insignia, and honors of the regiment. The banners of the household troops are, however, all crimson and richly embroidered with the royal insignia of England. Corresponding to the standards of the cavalry are the colors of the infantry regiments, of which each has "a pair," one, called the queen's color, being the union jack (q.v.), charged with some ornamental device; the other, the regimental color, with the cipher, number, device, motto, and honors of the corps, cantoned with a small union jack. When a regiment obtains new colors, they are usually given by the wife of the col. or some lady of distinction.

STANDARD, BATTLE OF THE, a battle between the English and Scots which took place on Cutton moor, near Northallerton, when the latter were defeated with great loss. On the usurpation of Stephen, David I. of Scotland, who, along with Stephen, had sworn to defend the rights of Matilda, daughter of Henry I., invaded England in pursuance of his oath, and compelled the barons of the northern part of the kingdom to swear fealty to that princess. After a war of nearly three years' duration, David encountered the English troops at Cutton moor, on Aug. 22, 1138, with a large but undisciplined army, who, partly in consequence of a rumor that the king was slain, were thrown into confusion, and the most disastrous rout followed, in which the Scots are said to have lost 10,000 men. The battle derived its name from the circumstance that a ship's mast, bearing on its summit the consecrated host, and surrounded by the banners of St. Peter of York, St. John of Beverly, and St. Wilfred of Ripon, elevated on a wagon, marked the center of the English army.

STANDARDS. In carpentry, the quarters or upright posts in wooden partitions are so called. The upright timbers to which doors are hung are called door-standards.

STANDING ORDERS is the name given to those permanent regulations which may be made by either house of parliament for the conduct of its proceedings, and are binding on the house by which they are made as continual by-laws enduring from parliament to parliament unless rescinded. A standing order of the house of lords, when rescinded, is said to be *vacated*; in the commons the corresponding term is *repealed*. In the lords, a motion for making or dispensing with a standing order cannot be granted on the same day that the motion is made, or till the house has been summoned to consider it; and every standing order, as soon as agreed to, is added to the "roll of standing orders," which is carefully preserved and published from time to time. In the house of commons there was, until 1854, no authorized collection of standing orders, except such as related to private bills. In that year a manual of rules, orders, and forms of proceeding relative to public business was drawn up and printed by order of the house.

Standing orders are occasionally suspended when it is desirable that a bill should be passed with unusual expedition.

STANDING STONES. Large rude unbewn blocks of stone, artificially raised to an erect position at some remote period, have been found in almost every part of the world where man has fixed his habitation. We find them in Britain, in continental Europe, in Assyria, India, Persia, and even in Mexico, and they are generally of such a size that their erection pre-supposes some degree of skill in the use of mechanical power. They are especially abundant in the British isles, where they sometimes stand singly, and sometimes in more or less regular groups; and it was long the general opinion of archaeologists that they were connected with the Druidical worship of the Celtic races. The result of modern investigation has been to throw doubts on the Druidical theory, while no other explanation has been given which is in all cases satisfactory. The erection of a large stone not easily shifted from its place is perhaps the earliest mode which man's instinct would contrive of preserving the memory of an event or of a hero; and there can be no doubt that many of these monoliths mark the site of a grave or of a battle-field. Human skeletons, and bronze, and iron weapons, have been in numerous cases found underneath them. A traditional remembrance of this origin is preserved in the name of "cat stane" (from Celtic *cath*, battle), given to some of them in Scotland, and "bauta stein" (battle stone) in Norway. Another possible purpose is preserved in the Scottish name of "hair stane," or boundary stone, by which they are occasionally known; not a few of them, whatever their original object, having been long used as landmarks, and being alluded to as such in very early charters. A third use of these monoliths is at least as old as the historical books of the Old Testament. We read in Judges ix. 6, of Abimelech being made king "by the pillar which was in Shechem,"

and in 2 Kings xi. 14, of Joash, when he was anointed king, standing "by a pillar as the manner was;" and a like usage prevailed in ancient Britain, where the king or chief was elected at the "Tanist stone" (from *Tunist*, the heir-apparent among the Celts), and there took a solemn oath to protect and lead his people. A very celebrated stone of this kind was the *lia fail* of Ireland, which was brought to Icolmkill for the coronation of Fergus Ere; and after being removed to Scone, became the coronation stone of Scotland, till conveyed away by Edward I. to Westminster, where it now forms part of the coronation chair of the sovereigns of the United Kingdom. In all these cases there is an idea of a solemn religious sanction attached to the stone; and a peculiar degree of sacredness seems to have invested any contract entered into at one of those perforated stones which are or were occasionally to be met with in England and Scotland. Such a stone, with an oval hole large enough to admit a man's head, till lately adjoined the monolithic group of Stennis in Orkney. It was known as the "stone of Odin," and continued till the middle of last century to be the scene of the interchange of matrimonial and other vows, he who broke the vow of Odin being accounted infamous. It is said to have been the popular belief that any one who had in childhood been passed through the opening would never die of palsy. The power of curing rheumatism was ascribed to a perforated stone at Madderty in Cornwall. While many of the monoliths in Britain are undoubtedly of a very remote age, there are some indications that the practice of erecting them continued for a time after the introduction of Christianity, and that they were used to subserve purposes connected with the new faith. A series of monoliths in the island of Mull are traditionally said to have been guide-posts to pilgrims visiting Iona, and it has been suggested that they point out the route which St. Columba must have pursued on his way to the residence of the Pictish king, Brude Mac Meilochon.

Still more puzzling to archæologists than the single monoliths are the large symmetrical groups of them, of which the most remarkable are Stennis in Orkney, Stonehenge and Avebury in Wiltshire, and Carnac in Brittany; all which, till lately, existed comparatively entire, though they have all been in the memory of the present generation more or less despoiled for building purposes. The most imposing of these monuments is Stonehenge (q.v.). At Stennis from 70 to 80 stones were grouped in two separate circles of 360 and 100 ft. diameter, respectively, the largest stones being in the smaller circle. At Avebury two double concentric circles were surrounded by an outer circle of 100 stones, the whole being approached by two long avenues of stones in double lines. In all these and other instances the circles were surrounded by a trench and mound. At Carnac the stones are placed not in circles but in straight lines, with a curved row at one end—an arrangement which has suggested the idea of a burial-place on the site of a great battle-field. All around Carnac, as well as Stonehenge, Barrows and Cromlechs (q.v.) are to be found. While the popular notion of all these monuments is that they were Druid temples, the circular form so frequent among them has also suggested that they may originally have been connected with sun-worship, and it is not impossible that they may have been used in turn for the successive religious worship of different races. They seem also to have served the purpose of courts of justice, or battle-rings for the duel and judicial combat. See **STONEHENGE**.

A remarkable description of monument, whose purpose is utterly unknown to us, is the *rocking-stone* (q.v.) or *logan-stone*. For a notice of a class of standing stones of considerable interest, ornamented with a peculiar description of sculpture, and found largely in Scotland, see **SCULPTURED STONES**.

STANDISH, MILES, 1584-1656; b. England; was a soldier in the Netherlands; was one of the emigrants who came to Plymouth in the *Mayflower* in 1620, though not a member of the Leyden church; showed great courage and energy, and was chosen military leader by the pilgrims in their wars against the Indians. His daring and skill awed the savages, and saved the settlements from their murderous assaults. During the first winter he lost his wife Rose. In 1625 he visited England as agent for the colony, returning in 1626 with supplies; was one of the proprietors and settlers of Duxbury, holding the office of magistrate or assistant for the town during the remainder of his life; took part in 1649 in the settlement of Bridgewater. His sword is in the Pilgrim hall, Plymouth. In Oct., 1872, the corner-stone of a monument to his memory was laid in Duxbury. The monument has been completed. It stands on Captain's Hill, a bold promontory on which Standish lived. It is a handsome circular stone tower 110 ft. high, surmounted by a statue of Standish. The view there is one of the finest on the coast. Longfellow has related the story of Standish in the poem, *The Courtship of Miles Standish*.

STANFIELD, WILLIAM CLARKSON, a distinguished painter, was b. of Irish parents, in the town of Sunderland, about 1793. At an early period of his life he went to sea, and made frequent long voyages, among which was that to China. In the China seas he passed some years of his life, and served for a time in the same ship with Douglas Jerrold—Stanfield in the capacity of a common sailor, and Jerrold as a midshipman. While thus engaged, Stanfield exhibited considerable talent both in painting and drawing. The first person of public note, however, to observe Stanfield's genius as a painter was the celebrated Capt. Marryat, who met with him in the Mediterranean, serving in a king's ship as captain's clerk. Stanfield and Marryat afterward became intimate; and

in 1840 the novelist employed the painter, then become famous, to illustrate his *Poor Jack*. Stanfield left the navy, in consequence of an injury to his feet, through a fall from the fore-topgallant mast-head of his ship. He then took to scene-painting as a means of earning his bread. His first efforts in this direction were made in the old Royalty theater, Wells street, Wellclose square, in the e. end of London, about the year 1818. He was afterward employed at Drury Lane theater, and here it is said that he produced some of his most extraordinary effects. He carried on this occupation until the year 1837, when he finally abandoned it, except on rare occasions. Stanfield, while painting for the theaters, had by no means neglected easel-painting. The first picture by him that attracted any considerable notice was "Market-boats on the Scheldt," exhibited at the British institution in 1826. The picturesque grouping, variety of figures, and gay costumes were much admired. His "Wreckers off Fort Rouge, Calais," exhibited in the following year, also at the British institution, was even more successful. In 1838 he obtained from the British institution a prize of fifty guineas for another of his pictures. In 1830 Stanfield made his first excursion on the continent, and in the same year exhibited at the academy his "Mount St. Michael, Cornwall," which placed him at once in the foremost rank as a marine painter. In 1833 Stanfield, in conjunction with David Roberts and others, founded the society of British artists. His election to the academy as associate took place in 1832; and in 1835 he was chosen R.A., in conjunction with sir William Allan. In 1833 Stanfield exhibited at the academy the first of a series of pictures of Italian scenery, painted for the marquis of Lansdowne for the banqueting-room at Bowater. In 1834 he commenced a similar series for the duke of Sutherland. In 1836 he exhibited "The Battle of Trafalgar," painted for the Senior United Service club; and in 1841 his celebrated "Castello d'Ischia," engraved by the art-union in 1844. In 1843 he sent to the academy "Mazerbo and Lucello, Gulf of Venice," said to be one of the finest landscapes he ever painted. "A Skirmish off Heligoland" (1867), was Stanfield's last contribution to the exhibitions of the academy, of which he was so distinguished a member. His great merit lies in the skillful combination of land and sea in the same view. Stanfield died on May 18, 1867.

STANFORD, LELAND, b. Watervliet, N. Y., 1824; descended from pioneers of 1720 who settled in the Mohawk Valley; educated at the public schools; studied law; was admitted to the bar in 1849, and practised law in Port Washington, Wis., until 1852, when he went into business with his brothers in Sacramento, Cal. He was a delegate to the republican convention at Chicago which nominated Abraham Lincoln for the presidency in 1860; governor of California, 1862-64; one of the projectors of the Pacific railroad, and president of the Central Pacific railroad company, and is prominent in railroad and financial matters on the Pacific coast; elected to U. S. senate, 1885. He founded the Leland Stanford Junior University at Palo Alto, California, in memory of his only son, opened in 1891. Senator Stanford died in 1893.

STANHOPE, CHARLES MAHON, third Earl of, 1753-1816; b. London; educated at Eton school and at Geneva; in 1774 married lady Hester Pitt, daughter of the earl of Chatham. In politics he was an advanced liberal, advocated republican ideas, and was known in the house of lords as the "minority of one." He is best known, however, for his mechanical inventions and improvements, the most important of which was the Stanhope printing-press. He also made some discoveries in regard to electricity, and introduced a new system of canal locks. Among his voluminous writings were: *Observations on Mr. Pitt's Plan for Reducing the National Debt*, *Rights of Juries Defended*, *Principles of Electricity*, etc.

STANHOPE, Lady HESTER LUCY, the eldest daughter of Charles, third earl Stanhope, and his wife Hester, daughter of the great lord Chatham, was b. Mar. 12, 1776. She grew up to be a woman of great personal charm, and of unusual force and originality of character. Very early she went to reside with her uncle, William Pitt, and as mistress of his establishment, and his most trusted confidant during his season of power, and till his death, she had full scope for the exercise of her imperious and queenly instincts. On the death of Pitt, a pension of £1200 a year was assigned her by the king. Mr. Fox proposed to provide for her much more munificently, but she proudly declined his offers, as unwilling to accept benefit at the hands of the political enemy of her dead uncle. The change from the excitements of a public career, as it might almost be called, to the life of an ordinary woman of her rank with means somewhat insufficient, was naturally irksome to her, and in 1808 she was tried still further by the death, at Coruna, of her favorite brother, Major Stanhope, and of sir John Moore, for whom she is known to have cherished an affection. The precise relations between them have never been made known; but the last words spoken by the dying hero were: "Stanhope" (a captain Stanhope of his staff, who stood by him) "remember me to your sister." Conceiving a disgust for society, she retired for a time into Wales, and in 1810 she left England never to return to it. In mere restlessness of spirit she wandered for a year or two on the shores of the Mediterranean, and finally settled herself among the semi-savage tribes of mount Lebanon. Here she led the strangest life, adopting in everything the eastern manners, and by the force and fearlessness of her character, obtaining a curious ascendancy over the rude races around her. She was regarded by them with superstitious reverence as a sort of prophetess, and gradually came so to consider herself. With the garb of a Mohammedan chieftain, she adopted something of the faith of one, and her

religion, which seems to have been sincere and profound, was compounded in about equal proportions out of the Koran and the Bible. Her recklessly profuse liberalities involved her in constant straits for money; and her health also giving way, her last years were passed in wretchedness of various kinds, under which, however, her untamable spirit supported her bravely to the end. She died in June, 1839, with no Frank or European near her, and was buried in her own garden. The main sources of information about her are the notes of the frequent travelers who visited her in her strange seclusion, and the *Memoirs* derived from her own lips, and afterward (3 vols. Lond. 1845-46) published by a medical gentleman who went abroad with her, and from time to time lived with her in her retirement.

STANHOPE, PHILIP HENRY, Earl, historian and biographer, was representative of a branch of the family of the Stanhopes, earls of Chesterfield. Its founder, a distinguished diplomatist in the reigns of William III. and Queen Anne, was son of the first earl of Chesterfield. James, first earl Stanhope, was an eminent military commander, who effected the reduction of Port Mahon, in the island of Minorca, and was the favorite minister of George I. His grandson, the third earl, distinguished for his scientific researches, and inventor of a printing-press which bears his name, died 1816. The subject of this notice, only son of the fourth earl, was born at Walmer, 1805. His courtesy title was viscount Mahon. He received a private education, but graduated at Oxford, where he took his B.A. degree, 1827; created D.C.L. 1834. He entered the house of commons in 1830. He was greatly instrumental in 1842 in securing the passing of the copyright (q.v.) act; was under-secretary for foreign affairs during the brief Peel administration, 1834-35; and secretary to the Indian board of control under the same minister, 1845-46. He was a moderate conservative in politics, and was warmly attached to sir R. Peel, who named him one of his literary executors. His contributions to history are numerous and valuable. Macaulay, in a review of one of his earliest works, the *War of the Succession in Spain*, accredits him with some of the most valuable qualities of a historian, viz., perspicuousness, conciseness, "great diligence in examining authorities, great judgment in weighing testimony, and great impartiality in estimating characters." His most considerable work is *A History of England from the Peace of Utrecht to the Peace of Versailles*, 1713-83, in 7 vols. His other works include a *Life of the Right Hon. W. Pitt*; a *History of Spain under Charles II.*; a *Life of the Great Condé*; a *Life of Belisarius*; a volume of *Historical and Critical Essays*; and a volume of *Miscellanies*. Of the *Life of Condé* it may be remarked that it was originally written by the author in the French language, and that the English work is really a translation, executed under his superintendence. In conjunction with the right hon. E. Cardwell he edited the *Memoirs of Sir R. Peel*; and he also published an edition of *Lord Chesterfield's Letters*. He was elected president of the society of Antiquaries, 1846; lord rector of the university of Aberdeen, 1858. He was mainly instrumental in procuring the appointment of the historical manuscripts commission. He was elected one of the six foreign members of the academy of moral and political sciences at Paris in 1872. His death took place at Bournemouth, Dec. 24, 1875.

STANISLAS, AUGUSTUS, King of Poland. See **POLAND**.

STANISLAS LESZCZYŃSKI, 1677-1766; b. Poland; elected to the Polish throne in 1704, and driven from it by the defeat of Charles XII. of Sweden, at Poltava, in 1709. He was a prisoner in Turkey, 1713-14. His daughter Maria married Louis XV. in 1725, and the latter, on the death of Augustus II. in 1733, began a war to place his father-in-law, who had been re-elected, on the throne. In 1735 Stanislas gave up his claims to the throne, but retained the royal name and estates, and was given the duchies of Bar and Lorraine, and a pension of 2,000,000 francs. He was a patron of literature and art.

STANISLAUS, a co. in central California; bounded on the n. by the Stanislaus river; drained by the Tuolumne and the San Joaquin rivers; on the Southern Pacific railroad; 1486 sq. m.; population '90, 10,040, chiefly of American birth. The surface is generally level, except in the w. where it is intersected by the Coast range. The soil is fertile. The principal productions are wheat, wool, and barley. Gold is found. Co. seat, Modesto.

STANISLA'WOW, or **STANISLAU**, a town and railway junction of Galicia, Austria, pleasantly situated between two branches of the Bistrica, 75 m. s.e. of Lemberg. It is the seat of active trade and manufactures. Pop. '90, 22,391.

STANLEY, a co. in S. Dakota, having the Missouri river for its e. boundary, and the n. fork of the Big Cheyenne for its n.; also drained by the Bad river; 1155 sq. m.; pop. 1890, 1028, chiefly of American birth. The surface consists of fertile rolling prairies. It has old fort George in the extreme s.e., and fort Bennett in the extreme n.e. Co. seat, Fort Pierre.

STANLEY, The Very Rev. ARTHUR PENRHYN, D.D., an eminent scholar and divine of the church of England, was the son of the late Edward Stanley, D.D., bishop of Norwich, and nephew of the late lord Stanley of Alderley. He was born Dec. 13, 1815, while his father was rector of Alderley, and resided there. Educated at Rugby under

the care of Dr. Arnold, he passed (1834) as an exhibitioner to Balliol college, Oxford, where he achieved a brilliant reputation, winning the Ireland scholarship, and taking a first class in classics (1837), the Latin essay prize (1839), and the English essay and theological prizes (1840). In 1838 he was chosen a fellow of University college, of which he was tutor and examiner for many years. Appointed canon of Canterbury (1851), professor of ecclesiastical history at Oxford (1856), canon of Christ church, and chaplain to the bishop of London (1858), he succeeded archbishop Trench in 1863 as dean of Westminster. He was also chaplain to the prince of Wales, and chaplain-in-ordinary to the queen. In 1863 he married lady Augusta Bruce, daughter of the 7th lord Elgin (died 1876). He was elected lord rector of St. Andrew's university in 1874. He visited the United States in 1878, and delivered several sermons and addresses. He died in London, July 18, 1881. Stanley was one of the most accomplished and liberal theologians of this age, and may be fairly regarded as the leader of the "broad church" party. In virtue of his literary genius, solid acquirements, and sympathetic and generous piety, he ranked among the most eminent of recent Christian teachers. His principal writings, besides his contributions to Smith's classical dictionaries, are the life of Dr. Arnold (1844); *Sermons and Essays on the Apostolical Age* (1847); *Memoir of Bishop Stanley* (1850); *The Epistles to the Corinthians* (1854); *Sinai and Palestine* (1855); *The Unity of Evangelical and Apostolical Teaching* (1859); *Lectures on the Eastern Church* (1861); *Lectures on the Jewish Church* (1863-65, 1876, 1879); *Sermons preached before the University of Oxford* (1860-63); *Historical Memorials of Westminster Abbey* (1867); *The Three Irish Churches* (2d. ed., 1869); *Essays on Church and State* (1870); *The Athanasian Creed* (1871); *Lectures on the History of the Church of Scotland* (1872); *Memoirs of Edward and Catherine Stanley* (1880); *Christian Institutions* (1881). His last literary work was done as a member of the assoc. for the revision of the Bible. He had a great love for Westminster Abbey, and did much to improve and popularize it; familiar with its every detail he delighted to act the cicerone for all classes of visitors. His great personal popularity was attested at his funeral, when all ranks of society, men of differing creeds and of no creed, gathered together to do reverence to the memory, not only of a great public man, but also of one whom they esteemed as a personal friend.

STANLEY, DAVID SLOANE, b. Ohio, 1828; graduate of West Point, 1852; distinguished himself in the war with the Comanche Indians, following them to their defeat in the Wichita mountains, 1859. At the beginning of the civil war he held the rank of capt. 4th cavalry, rising to maj. gen. of volunteers, 1862. After gallant service at Wilson's creek he was disabled by a fall from his horse, and on his recovery commanded the 2d division of the army of the Mississippi under Gen. Pope, performing effective service at Iuka and Corinth; chief of cavalry, army of the Cumberland, 1862; went with the expedition to Huntsville, Ala., crossed the Tennessee, and marched to the sea with Sherman. He was disabled on the field of Franklin, Tenn., where his presence saved the day. He was appointed col. 22d infantry U. S. A., 1866; brig.-gen., 1884; commander of the district of New Mexico and of department Texas, until his retirement, June 1, 1892.

STANLEY, The Right Hon. EDWARD HENRY SMITH, earl of Derby, an eminent English statesman, eldest son of the fourteenth earl of Derby (q.v.), was born at the family-seat, Knowsley Park, Lancashire, July 21, 1826; was educated at Rugby, and at Trinity college, Cambridge, where he concluded a distinguished university career by taking a first class in classics in 1848, together with a declamation prize and mathematical honors. He early adopted the profession of statesmanship, and especially applied himself to the study of social and economical questions. During his absence on a tour in Canada, the United States, and the West Indies, he was elected (Dec., 1848) M.P. for King's Lynn on the death of lord G. Bentinck. He afterward visited the east, and was still in India when his father received the queen's commands to form an administration in which Stanley was appointed under-secretary for foreign affairs. In 1855, on the death of sir W. Molesworth, lord Palmerston paid him the compliment of offering him the seals of the colonial office. The offer was declined; but in 1858 he was appointed to the secretaryship of the colonies in lord Derby's administration, and was soon called upon to succeed the earl of Ellenborough (q.v.) as president of the board of control for the affairs of India. The great Indian mutiny had not yet been quelled, and it devolved upon Stanley to frame resolutions and bring in a bill abolishing the East India company (q.v.), and transferring their Indian possessions to the direct government of the crown. This duty he performed with consummate ability. The great mutiny was put down during his secretaryship, and in Feb. 1859 he had to meet the legacy of financial disorganization which it bequeathed. The Derby government resigned before Stanley could carry out his plans for establishing the finances of India on a sounder basis; but he gave effective support to his successor in office, in reducing the military expenditure, and other measures of administrative improvement. In his father's third administration, formed in July, 1866, he was invested with the office of secretary of state for foreign affairs, and the ability and tact he displayed in conducting the negotiations for the settlement of the Luxemburg difficulty obtained for him a considerable amount of popularity. He continued in this office till the accession of the Gladstone ministry to power in 1868. In April, 1869, he was installed lord-rector of the university of Glasgow, and in October of the same year, on the death of his father, he took his seat in the house of lords. He was again made foreign secretary by Mr. Disraeli in 1874; but on account of

divergence from the views of the premier on the eastern question, he, like his colleague, the earl of Carnarvon, retired from the ministry early in 1878. He was distinguished by his support of workingmen's institutes, and of the cause of popular education. He was colonial secretary from 1882 to 1885. He joined the liberal unionists in 1886. He died in 1893.

STANLEY, HENRY MORTON, explorer; b. near Denbigh, Wales, 1841, was brought up and educated in a poorhouse; at the age of 14 shipped as a cabin-boy on a sailing vessel bound to New Orleans, and there was adopted by a merchant named Stanley, and took his name, his own being John Rowlands. He served in the confederate army; was taken prisoner, and then volunteered in the federal navy, becoming ensign in the ironclad *Ticonderoga*. After the war he became a newspaper correspondent, and as special writer for the *New York Herald* accompanied the English expeditions to Abyssinia and Ashantee in 1868. In 1869 he was commissioned by the proprietor of that paper to visit the interior of Africa and find the long-lost missionary and explorer Livingstone, and starting from Zanzibar in April, 1871, he met Livingstone at Ujiji on Nov. 10.

Under a joint commission from the *New York Herald* and the London *Daily Telegraph* Stanley started from the e. coast of Africa in 1874, circumnavigated the Victoria Nyanza, marched across country to the Albert Nyanza, and then coming s. again examined part of Tanganyika and its outlet toward the Lualaba. From Unyanyembe he pushed onward along the course of the Lualaba, supported by a large party of followers, and frequently having to repel violence by force of arms; and arriving at the mouth of the Congo in Aug., 1877, he proved that those surmises were correct which identified the Congo with the great and many-named river issuing from the lake country s.w. of Tanganyika.

He returned to England in 1877, but was soon placed in charge of the African International Association (q.v.), and labored in the Congo Free State till 1886. In 1887 he again sailed from England for Africa to rescue Emin Pasha, gov. of the Province of equatorial Africa, who by the revolt in the Soudan had been cut off from the rest of Egypt. Starting with a caravan from Matadi on the lower Congo, Mar. 21, he succeeded after great risk and hardship in reaching Emin Pasha, and when the latter was forced to retire from his post, guided him and his followers to the east coast, which was reached Dec. 3, 1889. During this expedition Stanley discovered that the Albert Edward and Albert Nyanza lakes were connected by the Semliki river, and that an arm of the Victoria Nyanza extends to within 155 miles of lake Tanganyika. Returning to England, he was given the degree of D.C.L. by Oxford university, was presented with the freedom of several cities, and on June 18 was appointed governor of the Congo Free State by the king of Belgium. On July 12 he was married in Westminster Abbey to Miss Dorothy Tennant, a Welsh lady and an artist of note. Stanley has pub. *How I Found Livingstone* (1872); *My Kalulu* (1872); *Coomassie and Magdala* (1874); *Through the Dark Continent* (1878); *The Congo* (1885); *In Darkest Africa* (1890); *My Dark Companions* (1893); *Slavery and the Slave Trade in Africa* (1893); *My Early Travels and Adventures in America and Asia* (1895). Since 1890 he has resided in England, and in July, 1895, was elected to Parliament from Lambeth.

STANLEY, THOMAS, 1625-78; b. England. He graduated from Cambridge in 1641, traveled in Europe, and studied law. He published *Poems and Translations*, and a *History of Philosophy*. In 1663 appeared his edition of *The Tragedies of Æschylus*, with Latin translation and a commentary. An edition of his poems was published in 1814 with a biographical memoir by Sir Egerton Brydges.

STANLY, a co. in central North Carolina, bounded on the e. and n.e. by the Yadkin river. Area, 390 sq.m.; pop. '90, 12,136. Co. seat, Albemarle.

STANNARIES (Lat. *stannum*, tin), the mines from which tin is dug. The term is most generally used with reference to the peculiar laws and usages of the tin mines in the counties of Cornwall and Devon. By an early usage peculiar to these counties, the prerogative of the crown, elsewhere reaching only to gold and silver mines, is extended to mines of tin, which are the property of the sovereign, whoever be the owner of the soil. A charter of King John to his tinners in Cornwall and Devonshire, of date 1201, authorized them to dig tin, and turf to melt the tin, anywhere in the moors, and in the fees of bishops, abbots, and earls, as they had been used and accustomed—a privilege afterward confirmed by successive monarchs. When Edward III. created his son, the Black Prince, duke of Cornwall, he at the same time conferred on him the stannaries of Devon and Cornwall, which were incorporated in perpetuity with the duchy. Their administration is committed to an officer called the lord warden of the stanneries, who has two substitutes or vice-wardens, one for Cornwall and one for Devon. In former times representative assemblies of the tinners (called parliaments) were summoned by the warden under a writ from the duke of Cornwall, for the regulation of the stannaries and redress of grievances; the last of them was held in 1752. The stannary courts are courts of record held by the warden and vice-warden, of the same limited and exclusive character as the courts-palatine, in which the tinners have the privilege of suing and being sued.

STANNIC ACID. See **TIN**.

STANOVOI, or **STANOWOI KHREBET** (Framework mountains), an extensive mountain chain in Siberia, in the extreme n.e. of Asia, forms the watershed between the rivers which flow n. into the Arctic ocean, and those which are tributary to the Amoor. The chain extends in an e.n.e. direction from the Transbaikal territory along the shores of the sea of Okhotsk, separating into several branches, one of which stretches e. to Behring's strait. Of this great mountain chain, the length of which is estimated at 2700 m., little is known further than that it is elevated and rugged, and that its peaks are covered with perpetual snow. The highest peak is Mt. Sokhondo, about 9250 feet.

STANSTEAD, a co. in s.e. Quebec, having lake Memphremagog for its w. boundary; drained by lake Massawippi in the n.; 408 sq. m.; pop. '91, 18,067. It is bounded on the s. by the state line of Vermont, and is intersected by the Central Vermont, the Boston and Maine, and the Grand Trunk railways. Co. seat, Stanstead.

STANTON, a co. in s.w. Kansas, having the state line of Colorado for its w. boundary; 672 sq. m.; pop. '90, 1031, chiefly of American birth. It is drained by branches of the Arkansas river. The surface is rolling, and adapted to grain culture and grazing. Co. seat, Johnson.

STANTON, a co. in n.e. Nebraska, drained by the n. branch of the Elkhorn river, Maple and Taylor creeks; 432 sq.m.; pop. '90, 4619, chiefly of American birth. The surface is undulating, thinly timbered, and adapted to grain culture and grazing. It is intersected by the Sioux City and Pacific railroad. Co. seat, Stanton.

STANTON, EDWIN McMASTERS, 1814-69; b. Ohio; of Quaker stock, originally from Culpeper co., Va.; graduated from Kenyon college in 1833. He entered a book-seller's store in Columbus, Ohio, where he remained but a brief time; studied law, and was admitted to the Columbus bar in 1836. He first practiced in Cadiz, Ohio, and became prosecuting attorney of the county; afterward practiced in Steubenville, Ohio; and in 1839-42, reported the decisions of the supreme court of the state. In 1848 he settled in Pittsburg, Penn., where he became the leader of the bar, and gained a high reputation for his masterly arguments in the case of the state of Pennsylvania vs. the Wheeling Bridge company. In 1856 he removed to Washington and practiced extensively before the U.S. supreme court. In 1858 he was in California acting as counsel of the United States in certain important land cases. After Mr. Lincoln's election in 1860, on the resignation of Mr. Cass from the cabinet, and the appointment of Mr. Black, then attorney-general, to succeed him, Mr. Stanton was appointed attorney-general. At the close of Mr. Buchanan's administration in the following March he retired with the other outgoing members of the cabinet; but in Jan., 1862, was recalled by Mr. Lincoln, and took the portfolio of secretary of war, in which office he sustained the burden of the vast war operations of the government to a degree that was not equaled by any other man. His administration was marked by a course of integrity, comprehensive judgment, determination, and force which won for him the admiration of his countrymen. He was in advance of the president in humanitarian leanings with regard to the negro, the severity of his nature being curiously softened in this connection. Mr. Lincoln viewed the integrity of the entire political system in his conduct of affairs, rather than any one element thereof, and it was not until after long effort on the part of Mr. Stanton that he was induced to specially entertain the negro question on its own merits, and to take that definite course which resulted in the emancipation act. Mr. Stanton continued a member of the cabinet under president Johnson's administration until May 26, 1868. His resignation occurred after a serious and painful imbroglio, which resulted in the impeachment of Mr. Johnson, which impeachment was not sustained on trial. Congress passed a vote of thanks to Mr. Stanton on his retirement. He resumed the practice of his profession, but his health was broken by his long and arduous labors, and he was speedily forced to retire from active employment. On Dec. 20, 1869, President Grant nominated him an associate justice of the supreme court, and he was at once confirmed by the senate. He died four days after this appointment.

STANTON, ELIZABETH (Cady), b. N. Y., 1815; married Henry B. Stanton in 1840. She attended the world's anti-slavery convention at London, where she met Lucretia Mott, with whom she signed the call for the first woman suffrage convention in 1848. This convention, which met at her house in Seneca Falls, N. Y., made the first formal demand for woman suffrage. She has addressed several constitutional conventions and congressional committees in England, Scotland, and the United States, and canvassed Kansas in 1867, and Michigan in 1874, in behalf of her cause. She was president of the first International Council of Women, held in Washington, 1888.

STANTON, HENRY BREWSTER, b. Conn., 1805; studied theology at Lane seminary; was delegate to the world's anti-slavery convention, London, 1840, and its secretary; admitted to the bar in Boston, 1842; removed to Seneca Falls, N. Y., 1848; was state senator, 1849 and 1851. He published *Reforms and Reformers of Great Britain and Ireland*, and for many years contributed to the *New York Tribune* and *New York Sun*. He was a popular anti-slavery lecturer. He d. 1887.

STANWIX, JOHN, 1690-1765; b. England; entered the army, 1706; became capt. of grenadiers, 1739; maj. of marines, 1741; lieut.col., 1745; equerry to Frederick, prince of Wales, 1749; made governor of Carlisle, and represented it in parliament, 1750; deputy

quartermaster gen. of the forces, 1754; sent to America as commander of the 60th, or royal Americans, and put in charge of the southern district with headquarters at Carlisle, Penn., 1757; made brig. gen.; was sent to Albany, 1758, and ordered to erect a fort at the Oneida carrying place, which in his honor was called fort Stanwix; returned to Pennsylvania, 1759; became maj. gen.; returned to England, and became member of parliament.

STANZA. See RHYME.

STAPELIA. See CARRION FLOWERS.

STAPHYLE A and **STAPHYLEA/CEÆ.** See BLADDER-NUT.

STAPHYLOMA (from the corresponding Greek word, derived from *staphylē*, a bunch of grapes, or, in this case, rather a grape at the end of a stalk) is a term employed by the oculist to signify any protrusion on the anterior surface of the eye. Staphyloma of the iris occurs when there is a protrusion of the iris through a perforation of the cornea, consequent either on ulceration or on a wound. Staphyloma of the cornea occurs when that coat of the eye is more or less completely destroyed, and when the cicatrix with which the iris has become covered is caused to protrude, by the pressure of the fluids of the eye, in the form of an opaque white prominence. It is unnecessary to enter into details of the treatment of these affections, which must be left entirely to the hands of the surgeon.

STAPLE (Ang.-Sax. *stapel*, a prop, support; a heap, and hence a place where goods are stored up or exposed for sale), a term applied, in the commerce of the middle ages, in the first instance, to the towns in which the chief products of a country were sold, and afterward to the merchandise that was sold at the staple towns. The staple towns, at first chosen from convenience, came in the course of time to be invested with important privileges. The staple merchandise of England has been enumerated as wool, wool-fells (i.e., sheep-skins), leather, lead, and tin, to which have sometimes been added butter, cheese, and cloth. Wool was, however, in point of fact, a far more important article of export than any of the rest, and was really the subject of those multitudinous regulations which fixed the staple in particular towns, both of England and of the continent. Goods intended for exportation had, in the first instance, to be exposed for sale at the staple town; the principal purpose of this regulation being, probably, to restrict commerce to those places where the officers who collected the king's customs could superintend it. Another object kept in view in the provisions made in the 13th and 14th centuries with respect to the staple was the encouragement of the resort of foreign merchants; indeed, greater privileges seem to have been accorded to the foreign than to the English merchants who attended the staple.

A tribunal of great antiquity, called the court of the staple, had cognizance of all questions which should arise between merchants, native or foreign. It was composed of an officer, called the mayor of the staple, re-elected yearly by the native and foreign merchants who attended the staple; two constables, appointed for life, also chosen by the merchants; a German and an Italian merchant; and six mediators between buyers and sellers, of whom two were English, two German, and two Lombard. The law administered was the *lex mercatoria*, and there was a provision that causes in which one party was a foreigner should be tried by a jury one-half of whom were foreigners. The most important legislative enactments regarding the staple and the court of staple were the statute of action Burnel (11 Edward I.), by which merchants were enabled to sell the chattels of their debtor, and attach his person for debt; 13 Edw. I. c. 3; and 27 Ed. III. c. 2, called the statute of staple, one object of which was to remove the staple formerly held at Calais to certain towns in England, Wales, and Ireland. With the growth of commerce the staples became more and more neglected, and at last fell altogether into disuse.

STAPLES, WILLIAM READ, 1798-1868, American historian and jurist, graduated at Brown university in 1817, became an associate judge of the Rhode Island supreme court in 1835, was chief justice of that court 1854-6, and from the latter year to the time of his death held the offices of secretary and treasurer in the Rhode Island society for the encouragement of domestic industry. He published the *Annals of Providence to 1834* (1843) and a *Documentary History of the Destruction of the Gaspe* (1845), besides editing several historical works.

STAPLETON. See STATEN ISLAND.

STAPLETON, SIR ROBERT, d. 1669, English author. He was brought up as a Roman Catholic and studied at Douai, but became a Protestant convert and gentleman usher to Charles II. He wrote translations of Juvenal and Musaeus and of French and Italian works. He was also the author of two plays, *The Slighted Maid* and *Hero and Leander*.

STAR, in heraldry. The star is of frequent occurrence as a heraldic bearing; it sometimes represents the heavenly body so called, and sometimes the rowel of a spur. In the latter case, it is blazoned a *mullet* (q.v.). Stars of more than five points should have the number of points designated, and the points may be wavy. A star, or *estoile*, with wavy points, is often designated a blazing star; and when the points are more than six in number, it is usual to represent only every second point as waved.

The star is a well-known ensign of knightly rank. A star of some specified form constitutes part of the insignia of every order of knighthood.

STAR, ORDER OF THE, an order of knighthood formerly existing in France, founded by John II. in 1350, in imitation of the then recently instituted order of the Garter in England. The ceremony of installation was originally performed on the festival of the Epiphany, and the name of the order is supposed to have been allusive to the star of the Magi.

STARAI'A-RUS'SA, a t. of Russia, in the government of Novgorod, 184 m. s.s.e. of St. Petersburg. The town is remarkable for its salt springs, which attract many visitors in summer. The means of communication between St. Petersburg and Starai'a-Russa, by the Moscow railway and the river Volkhov, are easy and rapid. Resident pop. '93, 15,673.

STAR ANISE. See **ANISE.**

STAR APPLE, *Chrysophyllum*, a genus of trees and shrubs of the natural order *sapotaceæ*. The species are natives of tropical and subtropical countries. The star apple of the West Indies (*C. cainito*) is a shrub of about 8 or 10 ft. high. The fruit is large, rose-colored, mixed with green and yellow; and has a soft sweet pulp of an agreeable flavor. Other species produce edible fruit.

STARBOARD. See **LARBOARD.**

STARCH, or **AMYLACEOUS MATTER,** $C_6H_{10}O_5$, is an organized substance of the class known as carbo-hydrates, which occurs in roundish or oval grains in the cellular tissue of certain parts of plants. It is very widely diffused through the vegetable kingdom, and is especially abundant in the seeds of the cereals, in the seeds of leguminous plants such as peas and beans, in the tuber of the potato, in the roots of arrowroot and tapioca, in the pith of the sago palm, etc. The grains of starch from the same kind of plant are tolerably uniform in size and shape, but vary in different species of plants from $\frac{1}{800}$ to less than $\frac{1}{8000}$ of an inch in diameter; and while some are circular or oval, others are angular; moreover, amongst other differences, some (chiefly the larger grains) exhibit a series of concentric rings, while in others no rings are apparent; and while the grains of potato starch, if illuminated by polarized light, with a Nicol's prism placed between the object and the eye, present a well-marked black cross; in wheat-starch no such cross is perceptible.

Ordinary commercial starch occurs either as a white glistening powder, or in masses which are readily pulverized; and when pressed between the fingers it evolves a slight but peculiar sound. It is heavier than water, and is insoluble in cold water, alcohol, and ether. If, however, it be placed in water at a temperature of 150° F. (65° C.), its granules swell from the absorption of fluid, and the mixture assumes a viscid, pasty consistence. Dilute acids rapidly induce a similar change, even without the agency of heat; and if heated with dilute sulphuric acid, the starch is first converted into dextrine, and finally into glucose or grape-sugar; and manufacturing chemists avail themselves of this property to obtain glucose on a large scale from starch. Starch dissolves in cold nitric acid, and on the addition of water to this solution, a white, tasteless, insoluble precipitate falls, which is known as *xylidine*, and explodes violently when struck by a hammer, or when heated up to about 350° F. (176° C.). The composition of this substance is not positively known, but in all probability one or two equivalents of the hydrogen of the starch (most probably two) are replaced by a corresponding number of equivalents of peroxide of nitrogen, NO_2 .

The reactions of starch with iodine and bromine are very remarkable. Iodine communicates to it a very beautiful purple color, and hence starch-paste serves as a delicate test for free iodine. The purple color which the iodine gives to the starch granules appears not to depend on a chemical combination, because on the application of heat the color disappears, and reappears on cooling. Bromine communicates a brilliant orange tint to starch—a reaction by which the presence of free bromine may be readily detected. When heated to a temperature of from 340° to 400° F. (171° to 204° C.), dry starch is converted into dextrine (q.v.), or British gum. At a higher temperature, it undergoes decomposition, and yields on dry distillation the same products as sugar. When heated in steam under pressure, it also passes into dextrine, and finally into glucose. The addition of a little sulphuric acid hastens these changes.

During the germination of seed, the starch undergoes a kind of fermentation, and is converted into a mixture of dextrine and glucose. This change is due to the action of a peculiar ferment termed diastase (q.v.), which exists in all germinating seeds during the process of growth, and is probably a mixture of albumen and gluten in a special stage of decomposition. Various animal matters, as, for example, saliva, pancreatic juice, the serum of the blood, bile, etc., exert the same action on starch as diastase. On prolonged exposure to the air, starch paste becomes acid, in consequence of the formation of lactic acid.

Starch is usually obtained by a simple mechanical separation of it from the other ingredients with which it is associated; advantage being taken of its insolubility in cold water. The details of the mode of separation vary according to the source from which it is procured. We extract from Miller's *Organic Chemistry* the method of procuring *potato-starch*: "This variety is prepared on a large scale from potatoes, which contain about 20 per cent. of amylaceous matter. The cellular tissue of the tuber does not exceed 2 per cent. of the mass; whilst of the remainder about 76 per cent. consists of

water, and the rest of small quantities of sugar, salts, and azotised matters. In order to extract the starch, the tubers are first freed from adhering earth by a thorough washing, and are then rasped by machinery. The pulp thus obtained is received upon a sieve, and is washed continuously by a gentle stream of water so long as the washings run through milky. This milkiness is due to the granules of starch which are held in suspension. This milky liquid is received into vats, in which the amylaceous matter is allowed to subside; the supernatant water is drawn off, and the deposit is repeatedly washed with fresh water until the washings are no longer colored. The starch is then suspended in a small portion of water, run through a fine sieve to keep back any portions of sand, and, after having been again allowed to settle, is drained in baskets lined with ticking. The mass is then placed upon a porous floor of half-baked tiles, and dried in a current of air, which is at first of the natural temperature; the drying is completed by the application of a moderate artificial heat" (pp.100,101). To obtain starch from wheat or rice, a more complicated process is required, as the large quantity of gluten which is associated with the starch in these grains requires to be removed either by fermentation, or, according to Jones's patent, by a weak alkaline solution, which dissolves the gluten, but does not effect the starch granules.

Commercially, there are two classes of starch—those used for food, and those used for manufacturing purposes. The former are treated under arrowroot (q.v.); the latter are chiefly made from wheat, rice, and potatoes; but in addition, large quantities of sago-starch are prepared in India, and sent to Europe, and small quantities are from time to time prepared from other sources, such as the fruit of the horse-chestnut, etc.

The importance of starch becomes at once obvious when we consider that it may be regarded as the starting-point in the preparation of brandy and other forms of spirit, and of beer and porter, and that it enters largely into the great *saccharine* group, constituting one of the leading subdivisions of food. See DIGESTION. It is, moreover, largely employed as an article of domestic use for laundry purposes, and also in the manufacture of dextrine and grape-sugar.

We shall conclude with a few words on starch in its physiological and medical relations. It might have been inferred *a priori* that starch was an essential article of diet, from the fact of its abundant occurrence in edible vegetables, even if the fact had not been established by numerous physiological experiments. Thus various kinds of potatoes yield from 12 to 27 per cent. of starch; peas, 32½ per cent.; beans, 34 to 36 per cent.; wheaten bread, 53½ per cent.; wheaten flour, 56½ to 72 per cent.; oatmeal, 59 per cent.; rye-meal, 61 per cent.; barley-meal, 67 per cent.; maize, 81 per cent.; rice, 83 to 85 per cent.; and it occurs in even larger proportions in arrowroot, sago, and tapioca. In a state of health, the proper diet consists in the due admixture of the albuminous, saccharine (or starchy), oleaginous, and saline groups; but in certain forms of disease, an excess or a diminution of the starchy element is expedient. Thus, in cases of weak gastric digestion, it is not advisable to mix starchy food with the albuminous, as it soaks up the too scanty gastric juice without making any use of it. In such cases, moreover, articles of food like potatoes, new bread, pastry, etc. are apt to turn acid in the stomach, and check digestion. There are, again, some cases of gastric disorder in which a purely starchy diet is expedient. Thus, according to Dr. Chambers, it is the best form of food "during acute catarrhal bilious attacks at the commencement of treatment, in even chronic gastric cases, and whenever a dusky complexion, hypochondriasis, or general distress show that arrested molting has caused a collection in the body of effete tissues" (*Dietetics in Clinical Lectures*, 4th ed., p. 539). In the early stages of rheumatic fever and other acute diseases, it is usually expedient to limit the diet of the patient for a day or two to a purely starchy diet, such as arrowroot, tapioca, panado, etc. In returning from a purely starchy to a mixed diet, Dr. Chambers suggests that such an arrangement shall be adopted as to prevent starchy and albuminous foods from being together in the stomach. For example, let the morning and evening diet be vegetable, with a mid-day meal of purely animal food. It should be recollected that although starch is converted into sugar by the saliva, pancreatic fluid, and intestinal juice (see DIGESTION), the change principally takes place from the action of the two last-named fluids in the small intestine. Hence, when the duodenum, jejunum, or ileum are morbidly affected, as in typhoid or enteric fever, in enteritis, in diarrhea, etc., little or no starch should be given in the food.

Wheat starch is the only variety of starch admitted into the pharmacopœia. It is employed in medicine chiefly in the form of mucilage (prepared by triturating 120 grains of starch with 10 fluid ounces of distilled water gradually added, and boiling for a few minutes, constantly stirring). This preparation is used either alone or as a vehicle for more active agents, as an enema, in dysentery, diarrhea, flatulent distention of the bowels, etc.; externally, it is used as an application to excoriations, to prevent bed-sores, etc., and as a basis for dusting-powders in various forms of discharging skin-diseases. Its use in surgery for the construction of immovable bandages has been noticed in the article SPLINTS.

STAR-CHAMBER, a tribunal of considerable note in English history, which met in the old council-chamber of the palace of Westminster, and is said to have its name from the circumstance that the roof of that apartment was decorated with gilt stars. It is

generally supposed to have originated in early times out of the exercise of jurisdiction by the king's council, acting as the *concilium ordinarium* and not *privatum*. The powers of the council, however, had been abridged by several acts of Edward III., and had altogether greatly declined when act 3 Henry VII. c. 1, either revived and remodeled them, or instituted, according to the view taken by Mr. Hallam, an entirely new tribunal. This statute conferred on the chancellor, the treasurer, and the keeper of the privy seal, with the assistance of a bishop and a temporal lord of the council, and chief-justices, or two other justices in their absence, a jurisdiction to punish without a jury, the misdemeanors of sheriffs and juries, as well as riots and unlawful assemblies. Act 21 Henry VIII. c. 20, added to the other members of the court the president of the council. Whether or not the above-cited act of Henry VII. meant to constitute a court distinct from the council, it is certain that, by the time of Elizabeth, the two jurisdictions were merged in one: and the resulting tribunal was, during the Tudor age, of undoubted utility as a means of bringing to justice great and powerful offenders who would otherwise have had it in their power to set the law at defiance. The civil jurisdiction of the star-chamber, at that period, comprised controversies between English and foreign merchants, testamentary causes, disputes between the heads and commonalty of corporations, lay and ecclesiastical, and claims to deodands. As a criminal court, it could inflict any punishment short of death, and had cognizance of forgery, perjury, riots, maintenance, fraud, libels, conspiracy, misconduct of judges and others connected with the administration of the law, and all offenses against the state, in so far as they could be brought under the denomination of contempts of the king's authority. Even treason, murder, and felony could be brought under the jurisdiction of the star-chamber, where the king chose to remit the capital sentence. The form of proceeding was by written information and interrogatories, except when the accused person confessed, in which case the information and proceedings were oral; and out of this exception grew one of the most flagrant abuses of this tribunal in the later period of its history. Regardless of the existing rule, that the confession must be free and unconstrained, pressure of every kind, including torture, was used to procure acknowledgments of guilt; admissions of the most immaterial facts were construed into confessions; and fine, imprisonment and mutilation inflicted on a mere oral proceeding, without hearing the accused, by a court consisting of the immediate representatives of prerogative. The proceedings of the star-chamber had always been viewed with distrust by the commons; but during the reign of Charles I., its excesses reached a height that made it absolutely odious to the country at large; and in the last parliament of that sovereign, a bill was carried in both houses (16 Car. I. c. 10), which decreed its abolition.

STAR-FISH, *Asteriada*, a family of *echinodermata* (q.v.) having in the center of the body a stomach with only one aperture, but extending, by two much-branched cæca, into each of the rays into which the body is divided. In some the central disk extends so as to include the rays, so that the general form is angular or lobed; in others the disk is very small in comparison with the length of the rays. Locomotion is effected by very numerous ambulacra (q.v.) placed in rows on the underside of the rays. A bony framework, of a vast number of pieces, extends to the extremity of each ray. The nervous system has its center around the mouth, and sends a filament to each ray. Star-fishes are hermaphrodite, and produce vast numbers of eggs, which are retained for a time under the body of the parent, resting on the points of its rays at the bottom of the sea, and raising up the center of the body, in order as it were to hatch them. The young are destitute of rays, and very unlike the mature form, so that their real nature was long mistaken. The mouth of star-fishes being on the under side, they seek their food—as indeed they perform all their motions—by crawling at the bottom of the sea, or on rocks, etc. They are very voracious, and are troublesome to fishermen by devouring their bait. They possess, in a very high degree, the power of reproducing lost members; a disk with a single ray left will reproduce the other rays and become a perfect star fish. More extraordinary is the readiness which many of them display, particularly those with long and slender rays, in breaking off these members. Some species—**BRITTLE STARS**—can scarcely be procured for a museum in a tolerably perfect state, because they throw off ray after ray, and, in fact, break themselves to pieces upon any alarm. Star-fishes abound in the seas of all parts of the world. Almost no object is more familiar on the sea-coast of America than the **COMMON STAR-FISH**, **CROSS-FISH**, or **FIVE FINGERS** (*Asterias* or *Uraster rubens*), thrown up on the beach by the tide, or thrown out of fishing-boats in harbors. Some of the species are much larger; and some exhibit very beautiful colors; whilst others are interesting from their structure—the long serpent-like form of their rays, or the division of the rays by successive forkings, so that the whole creature is a globular mass, the surface of which is formed of a countless multitude of living tendrils. See illus., **INVERTEBRATES**, vol. VIII., figs. 13, 22.

STAR-FORT, in field fortification, is a strong work consisting of alternate salient and re-entering angles, arranged on a regular or irregular polygon. It is a common work for defending an eminence on a battle field, or at the wing of a line, or as protection for the reserve-stores of an army.

STARGARD (Släv. *Starograd* or *Starigrod*, i.e., Old Town), a t. of Germany, province of Pomerania, is situated on the navigable river Ihna, 22 m. e. s. e. of Stettin, with

which, as with Posen and the whole east of Prussia, it is connected by railroad. Star-gard was formerly the capital of Lower Pomerania. Its manufactures include machinery, shoes, felt, soap, brushes, spirits and cigars. Pop. '90, 23,792.

STAR-GAZER, certain species of acanthopterous fishes of the genus *uranoscopus*. The eyes are near together on the top of the head, and therefore always looking upward, a circumstance to which they owe their name. They are spiny and ugly in appearance. In front of the tongue there is a long filament which can be protruded at will. The best known species are *u. scaber* of the Mediterranean, and *u. anoplos* of our South Atlantic coast, but most of the species are found in East Indian seas.

STARIN, JOHN HENRY, b. Sammonsville, N. Y., 1827; was a druggist in Fultonville, N. Y., 1845-48; became interested in shipbuilding and the transportation business, as well as in banking and stock-raising, and has greatly prospered. He was elected, as a repub., to the XLVth and XLVith congresses.

STAR JELLY. See Nostoc.

STARK, a co. in n.w. Illinois, intersected by the Rock Island and Peoria railroad and a branch of the Chicago, Burlington and Quincy railroad; 290 sq. m.; pop. '90, 9982, chiefly of American birth. It is drained by Spoon river, raising in its n. portion. The surface is hilly, containing beds of bituminous coal which is mined. Co. seat, Toulon.

STARK, a co. in s.w. N. Dakota, formed 1879; pop. '90, 2304. Area, 1310 sq. m. Co. seat, Dickinson.

STARK, a co. in n.e. Ohio, drained by the Nimishillen, the Sandy, and Sugar creeks; 560 sq. m.; pop. '90, 84,170, chiefly of American birth. It is intersected by the Cleveland terminal and Valley, the Cleveland, Canton, and Southern, and the Pennsylvania Co.'s railroads. Co. seat, Canton.

STARKE, JOHN, 1728-1822, b. N. H., a captain in the French and Indian war, who distinguished himself in the expedition to Ticonderoga in 1758. He was commissioned col. in 1775, and raised a regiment which was at Bunker Hill on the left of the American line. He joined the expedition against Canada, was at the front at Trenton and took part in the battle of Princeton. In 1777 he raised a new regiment in New Hampshire, but soon left it, thinking himself neglected by congress. At the head of New Hampshire troops he fought the battle of Bennington, Aug. 16, 1777, and was soon made brig.-gen., and thanked by congress, which had previously censured him for disobeying Gen. Lincoln's orders to march to the west. With a new force of New Hampshire recruits, he prevented Burgoyne's retreat from Saratoga. He commanded the northern department in 1778, and again in 1780, and was on the court-martial which condemned André.

STARKE, a co. in n.w. Indiana; drained by the Yellow and Kankakee rivers, the latter its n.w. boundary; traversed by the Pennsylvania Co.'s railroad; 300 sq. m.; pop. '90, 7339, chiefly of American birth. The surface is partly prairie and partly woodland, and diversified by small lakes; hay, corn, wheat, and cattle are staples. Co. seat, Knox.

STARKEY, THOMAS ALFRED, S.T.D., b. 1824, in Philadelphia: was educated for a civil engineer; but, having studied theology, was ordained priest in the Prot. Epis. church, 1848. He held pastorates at Troy, Albany, Cleveland, Washington, and Paterson, N. J.; and was consecrated bp. of Northern N. J., 1880.

STARLING, *Sturnus*, a Linnæan genus of birds of the order *insectorcs*; now the family *sturnide*; nearly allied to *corvidæ*, but in general of smaller size; the bill more slender and compressed, its point nail-like; the wings long and pointed. They are natives of almost all parts of the world, very generally gregarious, and some of them migratory. They feed on worms, insects, larvæ, and fruits. Some of them follow herds of quadrupeds, on account of the insects which attend them. The COMMON STARLING (*Sturnus vulgaris*) is a beautiful bird, rather smaller than the song-thrush or mavis, brown, finely glossed with black, with a pale tip to each feather, giving the bird a fine speckled appearance, particularly on the breast and shoulders; in advanced age it is more uniform in color. The plumage of the female is less beautiful than that of the male. Both sexes are more speckled in winter than in summer. The starling is abundant in most parts of Britain, and nowhere more so than in the Hebrides and Orkneys. It is very abundant in the fenny districts of England. It is found in all parts of Europe and throughout great part of Africa; and is also common in the n. of Asia. Starlings make artless nests of slender twigs, roots, and dry grass, in hollow trees, in holes of cliffs, under eaves of houses, or, readily enough, in boxes, which are often placed for them in trees or elsewhere near houses. They frequently breed twice in a season, and in autumn they unite in large flocks. The starling becomes very pert and familiar in confinement, displays great imitative powers, and learns to whistle tunes, and even to articulate words with great distinctness. Its natural song is soft and sweet.—The AMERICAN STARLING or MEADOW LARK (*S. ludovicianus*), is larger than the common starling. It is common in the United States, migrating northward in spring, and southward in autumn, and congregating in great flocks in autumn and winter. See *illus.*, LARKS, ETC., vol. VIII., fig. 11.

STAR-NOSE, *Condylura* or *Astromyctes*, a genus of the mole (q.v.) family, *talpidae* having much general resemblance to moles, but with a longer tail and an elongated slender muzzle, which bears at its extremity a remarkable structure of fleshy and somewhat cartilaginous rays disposed in a star-like form. The habits are very similar to those of moles. All the species of this genus are natives of North America. The best known is *condylura cristata*, which inhabits Canada and the eastern parts of the United States.

STARODOUB, a t. of European Russia, in the government of Tchernigov, and 100 m. n.e. of the town of that name. It stands in the middle of a fertile district, but at a distance from any commercial highway. Pop. '94, 25,294.

STAR OF BETHLEHEM, *Ornithogalum*, a genus of bulbous-rooted plants of the natural order *liliaceæ*, nearly allied to squills and hyacinths. The species are pretty numerous, natives almost exclusively of the eastern hemisphere, many of them of the cape of Good Hope, and some of the s. of Europe. The common star of Bethlehem (*O. umbellatum*), a native of France, Switzerland, Germany, the Levant, etc., is very common in flower-gardens. Its flowers are large, six to nine in a corymbose raceme, white and somewhat fragrant.

STAR OF INDIA, THE MOST EXALTED, THE ORDER OF THE, an order of knighthood instituted by queen Victoria in June, 1861, with the view of affording the princes, chiefs, and people of the Indian empire a testimony of her majesty's regard, commemorating her majesty's resolution to take on herself the government of India, and rendering honor to merit and loyalty. The order consists of the sovereign, a grand-master, who is to be the governor-general of India for the time being, and 25 knights, together with such extra and honorary knights as the crown may appoint. The members of the order are to be military, naval, and civil officers who have rendered important service to the Indian empire, and such native chiefs and princes of India as have entitled themselves to her majesty's favor. The insignia consist of a collar, badge, and star. The *collar* of the order is composed of the heraldic rose of England, two palm branches in saltire tied with a ribbon, and a lotus-flower alternating with each other, all of gold enameled, and connected by a double golden chain. From an imperial crown, intervening between two lotus-leaves, depends the *badge*, consisting of a brilliant star of five points, and hanging from it an oval medallion, with an onyx cameo profile bust of queen Victoria, encircled by the motto: "Heaven's light our guide," in gold letters, on an enriched border of light-blue enamel. The *investment badge* is similar to the collar-badge, but with the star, the setting of the cameo, and the motto all of diamonds: it is worn pendent from a ribbon of pale blue with white borders. The *star* of the order is a five-pointed star or mullet of diamonds on an irradiated field of gold. Around it, on an azure fillet bordered with gold, is the same motto in diamonds, the whole encircled by wavy rays of gold.

STARR, a co. in s. Texas adjoining Mexico, and bounded on the s. by the Rio Grande; about 2570 sq.m.; pop. '90, 1052, chiefly of American birth, with colored. Surface, prairie land, in which water and timber are scarce; sheep and cattle raising is the main occupation. Co. seat, Rio Grande.

STARR, MOSES ALLEN, an American neurologist, b. in Brooklyn, N. Y., May 16, 1854; educated at Princeton, the College of Physicians and Surgeons in N. Y., the universities of Berlin, Heidelberg, Vienna and Paris, he became, in 1886, professor of nervous diseases in the New York Polyclinic, and in 1888 professor of diseases of the mind and nervous system at the college of Physicians and Surgeons. He has published, *Familiar Forms of Nervous Diseases* (1890); *Lectures on Insanity* (1891); *Brain Surgery* (1893).

STARRS, WILLIAM, b. Ireland, 1807; studied Roman Catholic theology at Maynooth; came to America, 1828; entered the Sulpician seminary, Baltimore; was curate of St. Patrick's, New York, 1834-44; pastor of St. Mary's church, 1844-53; rector of St. Patrick's and vicar-general of the diocese of New York; had charge of the diocese from the death of archbishop Hughes, 1864, to the consecration of Dr. McCloskey. 'D. 1873.

STARS are distinguished from planets by remaining apparently immovable with respect to one another, and hence they were early called fixed stars, a name which they still retain, although their perfect fixity has been completely disproved in numerous cases, and is no longer believed in regard to any. Twinkling, or scintillation (q.v.), is another mark which distinguishes stars from planets.

The first thing that strikes the observer is the apparent daily motions of the stars. The greater part appear to rise in the e., describe smaller or greater arcs in the heavens, and set in the west; while others describe complete circles around a point n. of the zenith, that described by the so-called polar star being the smallest visible to the naked eye. These apparent motions arise from the rotation of the earth on its axis. Had the earth only this rotatory motion, the aspect of the starry heavens at any spot on the earth's surface would be the same at the same hour of the night all the year round; which is known not to be the case.

With few exceptions, the distance of the fixed stars is still unknown, and must in all be enormously great. Since the time of Bradley, many attempts have been made to measure what is called the *yearly parallax* of the stars, and thus determine their distances. When we consider that the motion of the earth round the sun brings us at one time a

whole diameter of its orbit (184 millions of miles) nearer to a particular region of the heavens than we were six months before, we should expect a change in the relative distances of the stars as seen from the two points—that as we approach them they should seem to separate. But no such change is seen to take place; and this was one of the early objections to the theory of Copernicus. The only answer that the Copernicans could give was, that the distance of the stars from us is so great that the diameter of the earth's orbit is as a point compared with it. The detection of the parallax of the fixed stars depended upon the perfection of instruments. The parallax of a star is the minute angle contained by two lines drawn from it, the one to the sun, the other to the earth. If that angle amounted to a second, the distance of the star would be 206,000 times that of the sun; and when the measurement of angles came to be reliable to a second, and still no parallax was discernible, astronomers could say that the distance of the nearest stars must be more than 206,000 times that of the sun—i.e., 206,000 times 92 millions of miles, or about 20 billions of miles. It is only since between 1832 and 1838 that anything like positive determinations of parallax have been made, chiefly by Henderson, Bessel, and Peters. The first published (Dec., 1838) was that of the double star 61 in the constellation of the Swan, by Bessel, who made the parallax $37''.0$, giving a distance over 550,000 times that of the sun, or 52 billions of miles, so that the light of this star is about $8\frac{1}{2}$ years in reaching the earth. The nearest of all the stars yet measured is α Centauri, the finest double star in the southern heavens, whose parallax was determined by Henderson and Maclear at the cape of Good Hope to be $0.9128''$ (the observations were made in 1832-33; the result read before the Astronomical society, Jan., 1839), or as subsequently corrected, $0.976''$, corresponding to a distance of about 20 billions of miles, and requiring $3\frac{1}{2}$ years for its light to reach us. To Sirius, the brightest of the stars, a parallax of $0.15''$, has been assigned, implying a distance six times that of α Centauri. "It has been considered probable, from recondite investigations, that the average distance of a star of the *first* magnitude from the earth is 986,000 radii of our annual orbit, a distance which light would require $15\frac{1}{2}$ years to traverse; and further, that the average distance of a star of the *sixth* magnitude (the smallest distinctly seen without a telescope) is 7,600,000 times the same unit—to traverse which, light, with its prodigious velocity, would occupy more than 120 years. If, then, the distances of the majority of stars visible to the naked eye are so enormously great, how are we to estimate our distance from those minute points of light discernible only in powerful telescopes? The conclusion is forced upon us that we do not see them as they appeared within a few years, or even during the lifetime of man, but with the rays which proceeded from them several thousands of years ago!"—Hind's *Astronomy*.

The stars have been divided into groups called constellations (q.v.) from the earliest times. The several stars belonging to the same constellation are distinguished from one another by Greek letters, beginning the alphabet with the brightest; and when these are not sufficient, by Roman letters and by numbers. Many of the most brilliant stars have special names. They are also divided according to their brightness into stars of the first, second, third, etc., magnitudes—a division which is necessarily somewhat arbitrary. The smallest stars discernible by a naked eye of ordinary power are usually called stars of the fifth magnitude; but an unusually sharp eye can discern those of the sixth and even seventh magnitude. All below are *telescopic* stars, which are divided in a very undetermined way down to the twentieth magnitude. Sir J. Herschel has determined that the light of Sirius, the brightest of all the stars, is 324 times that of a mean star of the sixth magnitude. By processes of photometric observation and reasoning, it is concluded that the intrinsic splendor of α Centauri is more than twice that of our sun, and that of Sirius 394 times. Among stars of the first magnitude in the northern hemisphere are usually reckoned Aldebaran (in Taurus), Arcturus (in Bootes), Atair (in Aquila), Betelgeux (in Orion), Capella (in Auriga), Procyon (in Canis Minor), Regulus (in Leo), Vega (in Lyra). In the southern hemisphere are Achernes (in Eridanus), Antares (in Scorpio), Canopus (in Argo), Rigel (in Orion), Sirius (in Canis Major), Spica (in Virgo), and α Centauri and α Crucis that have no special names.

No apparent magnitude, in the proper sense of the word, has yet been observed in any star. In the best and most powerfully magnifying telescopes, even the brightest stars of the first magnitude appear, not with small disks as all the planets do, but as luminous points without any visible diameter, and always the smaller the better the telescope. We are therefore totally ignorant of the real size of the fixed stars; nor could it be determined though we were sure of their distances, for the apparent diameter is an essential element in the calculation. We cannot, then, say whether the greater brilliancy of one star, when compared with another, arises from its greater nearness, its greater size, or the greater intensity of its light. It is certain that all the fixed stars are self-luminous. By the spectroscope several facts regarding their physical constitution have been made out; there are great differences in their spectra; the existence of several known elements is considered demonstrated. Sirius, e.g., contains hydrogen, sodium, and magnesium.

The number of the stars is beyond determination. Those visible by the naked eye amount only to a few thousands. Stars of the first magnitude are usually reckoned at 15 to 20, of the second at 50 to 60, of the third about 200, of the fourth at 400 to 500, of the fifth at 1100 to 1200. But in the following classes, the numbers increase rapidly, so

that stars of the sixth and seventh class amount to above 12,000. Stars are most dense in that region of the heavens called the Milky Way, which is mostly composed of stars of the eleventh and twelfth magnitudes. W. Herschel observed 116,000 stars pass the field of his telescope in a quarter of an hour, while directed to the densest part of the Milky Way.

That the fixed stars are not really immovable, as their name would imply, is seen in the phenomenon of *double or multiple stars* which are systems of two or more stars that revolve about one another, or rather about their common center of gravity. As they can be seen separate only by means of a telescope, and in most cases require a very powerful one, their discovery was possible only after the telescope was invented. Galileo himself discovered their existence, and proposed to make use of them in determining the yearly parallax of the fixed stars. After a long lapse of time, Bradley, Maskelyne, and Mayer again directed attention to the phenomena of double stars; but nothing important was made out respecting them till the elder Herschel made them the subject of a protracted series of observations, which led to the most remarkable conclusions as to their nature. The united observations of Struve, Savary, Encke, South, and especially those of Herschel the younger, continued for four years in the southern hemisphere at the cape of Good Hope, have raised the number of observed double, or rather multiple, stars to more than 6,000, of which the greater part are binary, or composed of two, but many are triple, some quadruple, and a few even quintuple, or consisting of five stars. The distance between the stars composing these systems is always apparently small (varying from less than 1" up to 32"); but apparent nearness does not always constitute a double star, for two really distant stars are not unfrequently so nearly in the same line, as seen from the earth, that they appear to be close together. In real multiple stars, the individuals are not only comparatively near to one another, but they revolve around one another. Among stars of the first three magnitudes, every sixth is a multiple star; among the smaller stars, the proportion is much less. In some cases, one of the stars is much larger than the other, as in the star Rigel in Orion, and in the polar star; but oftener the connected stars are nearly equal in luminous power. The two members of double stars are mostly of one color, but a difference of color is observed in about one-fifth of the whole number. In many of these cases, the one color is the complement of the other, and it is possible that the color of the smaller star may be subjective, arising from the action of the other upon the eye.

It was in 1803, after 20 years' observation, that sir W. Herschel advanced the view, which has been more and more confirmed since, that double stars are connected systems of two or more stellar bodies, revolving in regular orbits around one another, or rather round their common center of gravity. Their motions are found to follow the same laws as prevail in the solar system, and the orbits are elliptical. These distant bodies are therefore subject to the Newtonian law of gravitation. The period of revolution has, in several cases, been roughly approximated; among the shortest is that of ζ Herculis, estimated at 30 years; others are set down at hundreds. In cases where the parallax is known, the size of the orbits can be determined; and thus the astronomer is able to assert in regard to the double star 61 Cygni that the orbit described by these two stars about each other undoubtedly greatly exceeds in dimensions that described by Neptune about the sun. Even the masses of these stars have been calculated as being together 0.353, that of our sun being 1. It is a consequence of these revolutions that many stars are now seen double that formerly seemed single, and *vice versé*. If the plane of revolution have its edge presented to the earth, the stars will seem to move in a straight line, and at times to cover one another. The star ζ Herculis, seen by Herschel double in 1781, appeared single in 1802, and was first seen double again by Struve in 1826. The period of revolution is presumed to be 182 years.

The *proper motion* of stars, discovered by Halley, is of another kind. It consists in a displacement in various directions of the individual stars, so that the configuration of constellations is slowly changing. "The Southern Cross," says Humboldt, "will not always shine in the heavens exactly in its present form; for the four stars of which it consists move with unequal velocity in different paths. How many thousand years will elapse before its total dissolution cannot be calculated." The proper motions yet observed vary from $\frac{1}{20}$ of a second to 7.7". According to Bessel, the proper motion of the binary star 61 Cygni amounts to 5.123", so that in 360 years it would pass over a space equal to the moon's diameter. It must thus take thousands of years to alter sensibly the aspect of the heavens; although, taking into account the enormous distances, the actual velocities must be great. Of 3,000 stars observed by Bessel, 425 had a perceptible motion. Argelander has recently published a list of 560 stars having a proper motion.

It was first observed by sir W. Herschel that there is a perceptible tendency in the stars generally to diverge or open up in one quarter of the heavens, and to draw together in the opposite quarter; and this he attributed to a proper motion of our sun with his planets in the direction of the former point. The apparent motion thus caused is complicated with the real independent motions of individual stars. The point toward which this motion is directed, which is called the "solar apex," was fixed by Herschel in the constellation Hercules; and the result of subsequent and independent researches gives a nearly coincident point. The velocity has been calculated at upward of 150 millions of

m. a year, or 17,600 m. an hour—i.e., rather more than one-fourth of the earth's velocity in its orbit.

The spectroscope has been applied to investigate the physical constitution of the stars, with the result of identifying many of the elements composing our sun and earth. The spectra of the stars differ greatly among one another; some consisting mainly of simple lines, others having complex bands. The simple spectra are believed to indicate great intensity of heat, keeping the molecules of matter in a state of extreme dissociation; while the complex spectra show the molecules to be more associated in groups or compounds, owing to the repulsive force being less. The bluish stars are the hottest; a red tinge indicates comparative coolness. Our sun would seem to be a decaying star.

Several stars exhibit well-marked periodic alterations of a striking nature, and are hence called *variable stars*. A considerable number have been observed, of which the most remarkable are Mira (the "wonderful") in Cetus, and Algol in Perseus. The first attains its greatest luster every 334 days, and appears for 14 days as a star of the second and even at times of the first magnitude; it then decreases for two or three months, till it becomes of the sixth and even tenth magnitude, so as to be for half a year invisible to the naked eye and usually to telescopes. After this it begins again to increase, but more rapidly than it decreased. It is visible to the naked eye for three or four months of its period. Of all the variable stars yet observed in Perseus, Algol has the shortest period, being 68 hours 49 minutes. It appears for about 60 hours a star of the second magnitude, then decreases for four hours, and appears for a quarter of an hour of the fourth magnitude, after which it increases again for four hours. Various explanations have been offered of these mysterious appearances; the stars are supposed to turn on their axes, and to have their surfaces unequally luminous in different places; or a large dark body is assumed to be revolving about the luminous one, so as to intercept more or less of its light in different positions; or the stars are lens-shaped, etc. There is nothing, however, inadmissible in the supposition that the intensity of the light itself may vary; and if in other suns, why not in our own?

Allied to the variable stars are the *new* or temporary stars that appear suddenly in great splendor, and then disappear without leaving a trace. A number of instances are on record. It is not impossible that these also may be periodic.

Star Systems.—From the appearances connected with the Milky Way or Galaxy (q.v.), sir W. Herschel came to the conclusion that the stars forming our firmament do not extend indefinitely into space, but are limited in all directions, the mass having a definite shape. He conceived the shape to be something like that of a huge millstone, having one side cleft, and the two laminae set apart at a small angle. Let the diagram

FIG. 1.

(fig. 1) represent a vertical section of such a broad flat stratum, and suppose the solar system situated as at S, to a spectator looking on either side, in the direction of the thickness, as SB, the stars would appear comparatively sparse, but all round in the direction of the breadth (as SA) there would appear a dense ring, which would separate into two branches (SE, SD) in the direction of the cleft side. This supposition accounts for the appearance of the Milky Way, and all subsequent obser-

uations have tended to confirm the conjecture.

But this star system, which we may call our own, as our sun belongs to it, is but an item in the stellar universe. The appearances known as nebulae, in many cases, at least, are believed to be similar agglomerations of suns, separated from our system and from one another by unfathomable starless intervals (see NEBULÆ). Their forms are very various, but in general pretty well defined, and not without symmetry. A new star was discovered, in the center of the great nebula in Andromeda, Aug. 31, 1885.

STARS AND BARS. The flag of the Southern Confederacy as distinguished from the Stars and Stripes. It consisted of three horizontal bars of equal width—the two outer red, the inner white—and of a blue square in the upper corner by the staff, terminated by the lower red stripe. This square contained a circle of stars equal to the number of states. "The bars were by their colors, red and white, intended to express the qualities of courage and purity. The field of the union was blue, to express fortitude"—Jefferson Davis. This, the early flag of the Confederacy, was changed at least twice. See FLAGS.

STAR SPANGLED BANNER, THE, American national hymn, written by Francis Scott Key (1780-1843), on board the frigate *Surprise* during the bombardment of Fort M'Henry, Md., by the British, in 1814. He had gone there to release a friend captured by the enemy, but was not permitted to return to Baltimore. He witnessed the engagement all night, and at dawn when he saw the "Star Spangled Banner" still floating from the ramparts, he wrote the verses, which on his arrival in Baltimore, he had printed, with the direction that they should be sung to the tune of "Anacreon in Heaven," composed

in England by John Stafford Smith between 1770-75. The Star Spangled Banner was first sung in a tavern near the Holiday street theatre, Baltimore, by Ferdinand Durang. It is contained in Key's poems, published by Roger B. Taney (New York, 1857). Concert variations on this air for the organ were written by John Knowles Paine and by Dudley Buck. See Helen K. Johnson, *Our Familiar Songs* (New York, 1881).

STAR-THISTLE. See CENTAUREA.

STARVATION, or **INANITION**, are terms applied to the phenomena resulting from an entire deficiency, or an insufficient supply of food. From M. Chossat's well-known experimental investigations of this subject (*Recherches Expérimentales sur l'Inanition*, Paris, 1843), it appears that the average loss of weight in mammals and birds, between the commencement of fasting and the death of the animal, was 40 per cent, the loss varying above and below 40 per cent. in the different organs and tissues, as shown in the following table :

PARTS WHICH LOSE MORE THAN FORTY PER CENT.		PARTS WHICH LOSE LESS THAN FORTY PER CENT.	
Fat.....	93.3	Muscular coat of the stomach.....	39.7
Blood.....	75.0	Pharynx and Œsophagus.....	34.2
Spleen.....	71.4	Skin.....	33.3
Pancreas.....	64.1	Kidneys.....	31.9
Liver.....	52.0	Lungs.....	22.2
Head.....	44.8	Bones.....	16.7
Intestines.....	42.4	Eyes.....	10.0
Muscles of locomotion.....	42.3	Nervous system.....	1.9

Hence it appears that there is an almost complete removal of the fat, and a great reduction of the blood, while the nervous system is scarcely affected; and hence it would seem as if the supervention of death was coincident with the consumption of all the combustible materials of the body, and that previously the remaining nutritive force was concentrated on the nervous system.

The following are among the most prominent phenomena which Chossat observed either during the experiments or after the death of the animals: 1. Dropsical effusion. 2. Softening and destruction of the mucous membrane. 3. Blackening of the viscera, especially of the liver. 4. Bluish, livid, yellow, and reddish stains during life in the transparent parts of the skin. 5. Hectic fever, and a continuous decrease in the power of the body to resist cold. 6. At first a scanty excretion of dry, bilious, grass-green fæces, and afterward diarrhea of liquid saline matter. 7. Convulsions similar to those in death by hemorrhage. 8. Death by starvation seems to be in reality death by cold; since the temperature of the body is not much diminished until the fat is nearly consumed, when it rapidly falls, unless it be kept up by heat applied externally. 9. Young animals succumbed far sooner than adults. 10. The results of insufficient food were in the end the same as those of total deprivation; the total amount of loss being almost the same, but the rate being less, so that a longer time was required to produce it.

Chossat did not find that much influence was exerted on the duration of life by permitting or withdrawing the supply of water; but there is no doubt that in man, and probably in mammals generally, death supervenes much earlier when liquids as well as solid food are withheld. For a full account of the symptoms of starvation as they occur in the human subject, we must refer the reader to the writings on hygiene and forensic medicine of Orfila, Rostan, Caspar, Taylor, etc.; and especially to Dr. Donovan's account of the Irish famine of 1847, in the *Dublin Medical Press*, Feb., 1848, p. 67. The following are the most striking symptoms: In the first place, pain is felt in the stomach, which is relieved on pressure. The countenance becomes pale and cadaverous; the eyes are wild and glistening; the breath hot, the mouth parched, and the saliva thick and scanty. An intolerable thirst supervenes, which, if there be no access to water, becomes the most distressing symptom. The body becomes gradually emaciated, and begins to exhale a peculiar fetor, while the skin becomes covered with a brownish dirty-looking and offensive secretion almost as indelible as varnish, which Donovan at first mistook for encrusted filth. The bodily strength rapidly declines; the sufferer totters in walking, like a drunken man; his voice becomes weak and whining, and he is ready to burst into tears on the slightest occasion. In the cases recorded by Donovan, imbecility, and sometimes almost complete idiocy, ensued, but in no instance was there delirium or mania, which has been described as a symptom of starvation in cases of shipwreck. On examination after death, the condition of the body is such as might be expected from Chossat's experiments, viz., extreme general emaciation; loss of size and weight of the principal viscera; almost complete bloodlessness, except in the brain; and the gall-bladder distended with bile, which tinges the neighboring parts. Moreover, decomposition rapidly ensues.

It is impossible to fix the exact time during which life can be supported under entire abstinence from food or drink. Dr. Sloan has given an account of a healthy man, aged 65, who was found alive after having been shut up in a coal mine for 23 days, during the first ten of which he was able to procure a small quantity of foul water. He was in a state of extreme exhaustion, and notwithstanding that he was carefully nursed, he died three days after his rescue. Dr. Willan records the case of a young gentleman who, under the influence of religious delusion, starved himself to death. He survived for sixty days, during which time he took nothing but a little orange juice. In this

case, life was probably abnormally prolonged in consequence of the peculiar emotional excitement of the patient. Judging from the cases of abstinence owing to disease of the throat and impossibility of swallowing, Dr. Taylor infers "that in a healthy person under perfect abstinence, death would not commonly take place in a shorter period than a week or ten days."

It is worthy of notice that a deficient supply of food seems to check the elimination and removal of the effete materials of the body. This fact accounts not only for the tendency to putrescence, which is exhibited during the process of starvation, and for the rapidity with which putrefaction ensues after death, but for the pestilential diseases which almost always follow a severe famine; the excess of disintegrated matter in the blood rendering the system especially prone to the reception and multiplication of the diseases characterized as zymotic, such as fever, cholera, etc.

STASSFURT, a t. in Prussia, province of Saxony, on the Bode river, in the vicinity of the Hartz mountains, 20 m. s. of Magdeburg; pop. '95, 18,981. There are manufactures of chemicals, and much salt is produced in the neighborhood.

STATANT, in heraldry, a term applied to an animal standing still, with all the feet touching the ground. If the face be turned to the spectator, it is said to be *statant gardant*, or in the case of a stag, *at gaze*.

STATEN ISLAND, an island of New York, formerly constituting the co. of Richmond; after Jan. 1, 1898, constituting the borough of Richmond in the Greater New York. It is irregular in shape; extreme length, 13 miles; extreme breadth, 8 miles; area, about 60 sq. miles; bounded on the n. by the Kill von Kull, separating it from New Jersey, and by Newark bay, on the e. by New York harbor, on the s. by the lower New York bay; judicial seat, Richmond. On its e. shore at the Narrows are fort Wadsworth and a line of water batteries; on the n. shore is the Sailors' Snug Harbor, an asylum for aged and infirm seamen; and on its lower bay shore is South Beach, a summer resort. It is connected with New York and Perth Amboy, N. J., by steam ferries at St. George and Tottenville, is well supplied with steam and electric railroads; and by a bridge across the Arthur Kill. Its steam railroad joins the Baltimore and Ohio system at Elizabeth, N. J. The towns are Castleton (co-extensive with New Brighton villages), Middleton, Northfield, Southfield, and Westfield; the villages, New Brighton, Port Richmond, Edgewater, Tottenville, Linoleumville, Stapleton, and Tompkinsville. The island is a favorite residence place of New York business men, and has all the advantages of a large city. Pop. '90, 51,693.

STATEN ISLAND, an island off the s.e. point of Tierra del Fuego, from which it is separated by the strait of Le Maire. It is about 45 m. in length from e. to w. and about 10 m. at its greatest breadth, its shores much indented. Its eastern extremity is cape St. John, in lat. 54° 42' s., and long. 63° 43' west. The surface is mountainous, descending to the sea in steep slopes; its general character similar to that of Tierra del Fuego.

STATES, or **ESTATES**, in politics, the name given to the classes of the population who either directly or by their representatives take part in the government of a country. In all European countries where the northern conquerors established themselves, the rudiments of representative government appeared in the form of assemblies brought together to deliberate with the sovereign on the common weal. These assemblies at first consisted of the two estates of the clergy and the nobility or baronage, who together constituted the whole free population of the realm; the nobility including not merely the greater barons, but the whole freeholders. As the burgesses gradually emancipated themselves, and rose into importance, they formed a third estate. In France we find the *tiers état*, or citizens, recognized in the states-general (q.v.) in 1302. In Scotland the earliest occasion on which the burghs are mentioned as attending and concurring in a grant of taxation, is in the parliament held at Cambuskenneth in 1326, in which Robert Bruce set forth to the assembled estates the diminished condition of the royal income in consequence of the protracted struggle through which the country had come. The burgesses represented by the commissioners for the burghs, continued in Scotland to be a separate estate, and were not, as in England, amalgamated with the knights and lesser barons, who, in the Scots parliament, were always classed with the baronage. The lesser barons were, however, first allowed, and latterly enjoined, to appear by representatives; and the three estates of clergy, barons, and burgesses all sat and deliberated in one house. In England, on the other hand, the knights and lesser barons were at an early period separated from the greater barons, and conjoined with the burgesses into the third estate, which occupied a separate chamber from the lords spiritual and temporal. This peculiarity in the original constitution of the *tiers état* of England necessarily gave it a weight which it did not possess elsewhere, and exercised an important influence on the constitutional history of the country. As the peasants became emancipated, we also find them in some countries taking a share in the legislative power, either as a part of the *tiers état*, or, as in Sweden, forming a fourth estate. The four estates of nobles, clergy, citizens, and peasants were recognized in Sweden till 1866; and in the Swedish legislature, as constituted, each had its separate chamber. Throughout Europe, except in Russia (though in some small German states, such as Mecklenburg, the diet, representing only the landed gentry and the towns, has very little authority), the co-operation of the estates with the sovereign in the legislative power is more or less recognized. Some

assemblies have but one chamber, but more of them have two. The lower chamber is always wholly, or partly, elective, but sometimes consists of separate delegates from the different orders of the community, and has representatives of landed proprietors, of towns, of peasants, and of traders and manufacturers. The upper house or senate is in some constitutions hereditary; in some, it consists of members named by the sovereign or by the nobility, or some other class of the community, and often it combines these elements. In a few instances, as in Brazil, it is elected by the same constituency as the lower house, and differs only in the higher property qualification required of its members.

STATES EVIDENCE, a term in common use to describe the testimony of an accomplice in a crime against the other principals, given under an agreement, expressed or understood, with the prosecuting officer, that the informer shall go unpunished in consideration of his aid to the state. Such evidence is regarded as of little value if uncorroborated by other witnesses or circumstances; and it is usual for the court to instruct the jury that it is to be regarded with suspicion unless confirmed in material points by other testimony. It is for the states-attorney or other prosecuting agent to determine in what cases and with which parties an agreement can properly be made without compromising the interest of justice and good order.

STATES-GENERAL (Fr. *états généraux*), the name which was given to the convocation of the representative body of the three orders of the French kingdom; so named in contradistinction from the *états provinciaux*, or assemblies of the provinces. As far back as the time of Charlemagne, there were assemblies of clergy and nobles held twice a year to deliberate on matters of public importance; and in these assemblies the extensive body of laws bearing the name of the capitularies of Charlemagne was enacted. The succeeding centuries, however, were adverse to free institutions; and these national convocations, becoming gradually less important, seem to have ceased to be held about 70 years after Charlemagne's death. From that time forward, there is no trace of any national assembly in France till 1302, when the *états généraux*, including the three orders of clergy, nobles, and citizens, were convened by Philippe le Bel, with the view of giving greater weight to the course adopted by the king in his quarrel with pope Boniface VIII. In 1314 we find the states-general granting a subsidy: during the reigns of Philippe IV. and his successor, the imposition of taxes by arbitrary authority was the subject of general discontent; and in 1355 the states were strong enough to compel the government to revoke the taxes so imposed. The states-general, however, though their consent seems in strictness to have been considered requisite for any measure imposing a general taxation, had, unlike the assemblies under the Carolingian kings, no right of redressing abuses except by petition, and no legislative power. Under Charles VI. and Charles VII. the states-general were rarely convened, and it was often found more convenient to ask supplies from the provincial states. But as the royal authority increased, the formality of any convention of states general or provincial gradually ceased to be regarded as indispensable, and a final and unsuccessful struggle for immunity from taxation took place at the states-general of Tours in 1484. Louis XIII. convoked the states-general, after a long interval, in 1614, but dismissed them for looking too closely into the finances; and from that time down to the revolution, the crown, with the tacit acquiescence of the people, exercised the exclusive powers of taxation and government. In 1789 the memorable convention of the states-general took place, which ushered in the revolution. As soon as they had assembled, a dispute arose between the two privileged orders and the third estate as to whether they should sit and vote in one chamber or separately. The *tiers état*, of its own authority, with such deputies of the clergy as chose to join them—none of the nobles accepting their invitation—assumed the title of the *assemblée nationale*, a name by which the states-general had previously been sometimes designated. See ASSEMBLY NATIONAL.

The name states-general is also applied to the now existing legislative body of the kingdom of the Netherlands (q.v.). It is so called in contradistinction from the provincial states, which are legislative and administrative assemblies for the several provinces.

STATES, NAMES OF.

ALABAMA is an Indian word meaning "here we rest." When the Creek Indians were driven from their hunting grounds in what is now southern Georgia, they fled westward to the banks of a river, where they halted with the exclamation, "Alabama!"

ARKANSAS was named from the "Kansas," an Indian tribe living in that section, and the French prefix "Arc."

CALIFORNIA is a name given by Cortez to all the region north of Mexico, and he is said to have named it from an old Spanish island in romance, the name signifying "an abundance of gold." Others claim it to have originated from the Spanish *caliente formalla*, meaning "hot furnace."

COLORADO is a Spanish word signifying "colored" or "ruddy;" the name was first given to the river on account of the reddish tint of its waters.

CONNECTICUT is named from the Mohican name for the river, *Quonektacut*, meaning "long river."

DAKOTA is a Sioux word signifying "leagued," "allied," or many in one government, referring to the numerous Sioux tribes under one chief.

DELAWARE was named after Thomas West, Lord de la Warr.

FLORIDA was named by Ponce de Leon to commemorate the day of his discovery, *Pasquas de Flores*, or, Feast of Flowers, or, as we call it, Easter Sunday.

GEORGIA was named in honor of George II. of England.

IDAHO is an Indian word meaning the "Gem of the mountains."

ILLINOIS was named after a tribe of Delaware Indians who were called *Illini*, meaning real or superior men, to which was added French *ois*.

INDIANA was named from the word "Indian."

IOWA is the French form of an Indian word meaning the "sleepy ones"—the name of an Indian tribe.

KANSAS is an Indian word signifying "smoky waters," and the state was named from an Indian tribe.

KENTUCKY is from the Indian word *Kantuckkee*, meaning "the dark and bloody ground," in allusion to the bloody fights that used to occur between the tribes who used it as a hunting ground.

LOUISIANA was named in honor of King Louis XIV. of France.

MAINE was named from the province of Maine in France.

MASSACHUSETTS is an Indian word meaning "blue hills."

MARYLAND was named in honor of Henrietta Marie, Queen of Charles I. of England.

MICHIGAN was named from the lake. The word is from two Indian words—*mitchi*, great, and *sawegyan*, lake.

MINNESOTA is an Indian word from the Dakota language meaning "cloudy or sky-tinted waters."

MISSISSIPPI is from two Indian words of the Natchez language, *Miche Sepe*, great river, or, as the Indians called it, the "Father of Waters."

MISSOURI is an Indian word meaning "Mud River;" the state was named from the river.

MONTANA is named from the high mountains that traverse her borders.

NEBRASKA is an Indian word meaning "shallow water and flat country."

NEVADA is a Spanish word signifying "snow clad."

NEW HAMPSHIRE was named from the province of Hampshire, England, originally called *Laconia*.

NEW JERSEY was named after the Isle of Jersey, as a mark of esteem to Sir George Carteret.

NEW YORK was first named New Netherlands, afterwards, New York, in honor of the Duke of York.

NORTH CAROLINA, in honor of Charles II. of England.

OHIO is from an Indian word meaning "very white and beautiful with froth," though some authorities assert that it means "river of blood."

OREGON is an Indian word meaning "fine river of the west." Some assert, however, that the name of the state is derived from the Spanish *oregano*, or wild marjoram, which grows abundantly throughout that section.

PENNSYLVANIA named by William Penn, "Sylvania" or *Forest-land*, to which King Charles II. prefixed "Penn" in honor of Penn's father.

RHODE ISLAND, name first given to the island on which Newport is built, because it looked like the Island of Rhodes in the Mediterranean; others assert that it was named *Roodt Eylandt* from the Dutch, because its shores looked red.

SOUTH CAROLINA, same as North Carolina.

TENNESSEE, from the Indian *Tannasse*, or "River of the Big Bend."

TEXAS is from the Indian *Texas*, signifying "Paradise."

VERMONT is named from two French words, *vert*, green, and *mont*, mountain.

VIRGINIA was named from Queen Elizabeth, who delighted in being called the "Virgin Queen."

WASHINGTON was named after George Washington.

WEST VIRGINIA was formed from the western part of Virginia, and retained the name with the prefix "West."

WISCONSIN is an Indian word meaning the "wild, rushing river."

WYOMING is an Indian word meaning "wide plain."

ALASKA is a corruption of the Indian *Alakshak*, or the "Great Land."

ARIZONA is an Indian word meaning "Blessed Sun."

NEW MEXICO. The word Mexico is formed from *Mexitli*, the name of one of the gods of the Aztecs. Some assert, however, that the word means the "Habitation of the God of War."

UTAH is an Indian word meaning "Contented People." The Mormons call the territory *Deseret* signifying "Virtue and Industry."

STATES, POPULAR NAMES OF.

BADGER STATE. Wisconsin, from the numbers of that animal during its early history.

BAYOU STATE. Mississippi, from the number of bayous or channels within its boundaries.

BEAR STATE. Arkansas, on account of the great numbers of that animal with which it was infested during its early history.

BEAVER STATE. Oregon, from the early fur-trade originally carried on by John Jacob Astor.

BLACK WATER STATE. Nebraska.

BLIZZARD STATE. South Dakota, because of its storms.

BLUE GRASS STATE. Kentucky.

BLUE HEN STATE. Delaware; the name originated during the Revolutionary War, when the commander of a corps, who was a veteran cock-fighter, always bet on the "blue hen's chickens" (his favorite breed of fighters). From this the name came to be applied to the members of his corps, and subsequently to the state.

BLUE LAWS, *Land of*. Connecticut. See BLUE LAWS.

BUCKEYE STATE. Ohio, because the horse chestnut, which grows in great profusion, is commonly called *buckeye*.

BULLION STATE. Missouri, from the sobriquet "Old Bullion" given one of its senators, Mr. Benton. When the charter of the U. S. Bank expired in 1836, he was very outspoken in his financial policy, and made many speeches in which he strongly urged the adoption of gold and silver currency, as the only true remedy for the financial difficulties of the times.

CENTENNIAL STATE. Colorado, because it was admitted into the Union in 1876, or Centennial Year.

CENTRAL STATE. Kansas, a name which seems particularly applicable, not only on account of its geographical position, but also its position in the history of the nation, since it was the Kansas struggles that hastened the climax in politics.

CORN CRACKER STATE. Kentucky, the poor whites being frequently called "Crackers."

COTTON STATE. Alabama.

CRACKER STATE. Georgia; see above.

CREOLE STATE. Louisiana, because of the large proportion of Creoles among its inhabitants.

DIAMOND STATE. Delaware, because of its minute size, and, consequently, its supposed extreme importance.

DOWN EAST. Maine; see DOWN EAST.

DOMINION. New Jersey. In 1817, the legislature passed an act whereby Joseph Bonaparte, ex-king of Spain and an alien, could hold real estate. Shortly after this he built a magnificent summer home at Bordentown, and spent much time there. This rather aroused the envy of sister states, who accused the Jersey people of having left the Union to be under the rule of an ex-king.

EL DORADO. California, "golden land."

EMPIRE STATE. New York.

EMPIRE STATE OF THE SOUTH. Georgia.

EXCELSIOR STATE. New York, from the motto on its coat-of-arms.

FREESTONE STATE. Connecticut, from its freestone quarries.

GARDEN OF THE METROPOLIS. New Jersey, from its innumerable fruit and market gardens.

GEM OF THE MOUNTAINS. Idaho.

GOLDEN STATE. California.

GOPHER STATE. Minnesota, from the numbers of that animal.

GRANITE STATE. New Hampshire, from its mountains of granite, said to be visible thirty miles out at sea.

GREEN MOUNTAIN STATE. Vermont, from its mountains.

GULF STATE. Florida, from its location.

HAWKEYE STATE. Iowa, from an Indian chief, Black Hawk, who lived within its territory.

HOOSIER STATE. Indiana; the word is said to have been originally *husher*, a common term in the west for a bully, and was applied by New Orleans merchants to all Indiana boatmen, on account of their rude and boisterous manners and braggadocio air. Another version of the origin is that Kentuckians gave the name to their neighbors from their peculiar way of saying "Who's yere," when they heard a knock at the door.

KEYSTONE STATE. Pennsylvania, because if the names of the thirteen original states be arranged in the form of an arch, Pennsylvania will occupy the position of the keystone of the arch.

LAKE STATE. Michigan, on account of position.

LAND OF FLOWERS. Alabama.

LAND OF STEADY HABITS. Connecticut; see BLUE LAWS.

LITTLE RHODY. Rhode Island, on account of diminutive size.

LONE STAR STATE. Texas, from the device on its coat-of-arms.

LUMBER STATE. Maine, from its immense forests.

MOTHER OF STATES. Virginia, because first settled of the thirteen original states.

MOTHER OF PRESIDENTS. Virginia, because the birthplace of six presidents.

NEW ENGLAND OF THE WEST. Minnesota, because largely settled by emigrants from New England.

NUTMEG STATE. Connecticut, because its inhabitants have the reputation of being so ingenious and shrewd, that it has been said of them, they can make nutmegs out of wood and sell them to unsuspecting purchasers.

OLD BAY STATE. Massachusetts, from the Colony of Massachusetts Bay, which was called "Old Bay" colony before the adoption of the state constitution.

OLD DOMINION. Virginia was named in early colonial history "Old Virginia" to distinguish from the New England colonies, which were frequently spoken of as "New Virginia." The state documents sent by the king to the governor were always headed to the "Colony and Dominion" of Virginia, and Old Dominion came finally to be a very common term in the papers and the conversation of the day.

OLD FRANKLIN STATE. Tennessee, in allusion to its name of Franklin from 1785 to 1788.

OLD LINE STATE. Maryland, having reference to boundary settlements between Lord Baltimore and William Penn.

OLD NORTH STATE. North Carolina.

PALMETTO STATE. South Carolina, from its coat-of-arms.

PANHANDLE STATE. West Virginia, from the irregular section of the state lying between the Ohio river and the western boundary of Pennsylvania.

PELICAN STATE. Louisiana, from its coat of-arms.

PENINSULAR STATE. Florida.

PINE TREE STATE. Maine, from its extensive forests.

PRAIRIE STATE. Kansas.

SAGE-BRUSH STATE. Nevada, from the immense growth of sage-brush on the plains.

SILVER STATE. Nevada, from the supposed wealth of its silver mines.

SUCKER STATE. Illinois, from an incident common in the days of the early emigrants. The prairies are full of holes made by the crawfish in its search for fresh water, and emigrants, in crossing these prairies, were careful to provide themselves with long hollow reeds with which to draw (suck) water from one of these holes.

SUNFLOWER STATE. Kansas, from the numbers of wild sunflowers.

TURPENTINE STATE. North Carolina.

VOLUNTEER STATE. Tennessee.

WOLVERINE STATE. Michigan.

STATE—STATE RIGHTS. The term state has a rather indefinite application in several directions; originating, however, in each instance, in the attribute of concentration, or organization; assumed possibly, in the instance of a people, for the purpose of self-preservation or defense. By a very common movement in language, the term becomes also applicable to the method or form employed for carrying out the original design. Thus a state is an organized body, made up, perhaps, of different races and different speaking peoples; having the object of union under one system of government and one general policy. And *the state*, in that instance, would be the actual system of government and policy, which ruled the body in question. Thus, Louis XIV.—"*L'état, c'est moi.*" In the case of the United States, the entrance into that condition was a transition from that of provinces, or colonies; and, therefore, more readily accomplished than it could otherwise have been. The concentration and organization were there, and it was only necessary to endow these with the functions of self-government and a systematic policy, to create a state.—The question of "state rights," is one which occurred after the confederation and on the formation of a more perfect union. Certain of these rights being withdrawn from the states and given to the general government, the actual condition of independence in their case was just so far vacated. It became a question, so far as rights still vested were concerned, whether or not these were perpetual, or if they could also be withdrawn on the application of a similar process, or in the natural order of things under the new system. As to this, the most learned expounders of constitutional law are at issue; and the point becomes, in fact, one to be decided in the case of instances as they arise, and with a due regard for national and interstate, as well as individual relations.

STATIC ELECTRICITY. See **ELECTRICITY, STATIC.**

STATICS (Gr. root *sta*, to stand), the science of the equilibrium or balancing of forces on a body or system of bodies, has gradually advanced from the days of Archimedes to the vast developments it has now acquired. Singularly enough, though most of its simpler theorems are very generally known, are almost popular, in fact, there is no science in which elementary teaching is so defective. The ordinary proofs of its fundamental principles, such as the *parallelogram of forces*, the *principle of the lever*, etc., are usually founded on the supposition that a body in equilibrium is *absolutely at rest*. Now, any one who knows that the earth rotates about its axis, that it revolves about the sun, that the sun is in motion relatively to the so-called fixed stars; that *they* are in all probability, in motion about something else which is itself in motion, etc., will at once see that there is no such thing as absolute rest, and that *relative rest* or *motion*, unchanged with reference to surrounding bodies, is all that we mean by equilibrium. He will then, at once, see that the foundations of statics are to be sought in the Laws of Motion (q.v.). And, in fact, Newton's second law of motion gives us the necessary and sufficient conditions of equilibrium of a single particle under the action of any forces; while his third law, with the annexed scholium, gives these conditions for any body or system of bodies whatever.

The simplest statement of the conditions of equilibrium of a rigid body which can be given, is that furnished by this scholium of Newton's, which is now known by the name of the principle of energy (see FORCE) or work (q.v.). It is as follows: A rigid body is in equilibrium if, and is not in equilibrium unless, in *any* small displacement whatever, no work is done on the whole by the forces to which it is subject. In the case of what are called the *mechanical powers* (q.v.), this is equivalent to the statement that work expended on a machine is wholly given back by the machine—or that the work done by the *power* is equal to the work spent in overcoming the *resistance*.

It is shown in the geometrical science of kinematics that any motion whatever of a rigid body can be reduced to *three* displacements in any three rectangular directions, together with *three* rotations about any three rectangular axes—so that the equilibrium of a rigid body is secured if no work be done on the whole in any of these *six* displacements. There are thus six conditions of equilibrium for a rigid body under the action of any forces—and these are reduced to *three* (two displacements and one rotation), if the forces are confined to one plane; and to *one* (a displacement) if the forces act all in one line.

Equilibrium may be *stable*, *unstable*, or *neutral*. It is said to be stable if the body, when slightly displaced in any way from its position of equilibrium, and left free, tends to *return* to that position. It is unstable if there is any displacement possible which will leave the body in a position in which it tends to *fall further away* from its position of equilibrium. It is neutral if the body, when displaced, is still in equilibrium. It is easily shown, but we cannot spare space for the proof, that a position of stable equilibrium is, in general, that in which the potential energy (see FORCE) of the body is a minimum—of unstable equilibrium, where it is a maximum (for some one direction of displacement at least)—of neutral equilibrium, where the potential energy remains unchanged by any small displacement. Thus a perfect sphere, of uniform material, is in neutral equilibrium on a horizontal plane—while an oblate spheroid, with its axis of rotation vertical, is in stable equilibrium; and a prolate spheroid, with its axis vertical, is in unstable equilibrium on the plane. Similar statements hold for other than rigid bodies. Thus, a chain, or a mass of fluid, is in stable equilibrium when its potential energy is least, i.e., when its center of gravity is as low as possible.

STATIONS (Lat. *statio*), a name applied in the Roman Catholic church to certain places reputed of special sanctity, which are appointed to be visited as places of prayer. The name is particularly applied in this sense to certain churches in the city of Rome, which, from an early period, have been appointed as churches which the faithful are particularly invited to visit on stated days. The names of these churches are found on the several days in the Roman missal prefixed to the liturgy peculiar to the day. The word, however, is employed in a still more remarkable manner in reference to a very popular and widely-received devotional practice of the Roman Catholic church, known as that of "the stations of the cross." This devotion prevailed in all Catholic countries; and the traveler often recognizes it even at a distance by the emblems which are employed in directing its observance—the lofty "Calvary" crowning some distant eminence, with a series of fresco-pictures or bas-reliefs arranged at intervals along the line of approach. These representations, the subjects of which are supplied by scenes from the several stages of the passion of our Lord, are called stations of the cross, and the whole series is popularly known as the *Via Calvaria*, or way of Calvary. The origin of this devotional exercise, like that of local pilgrimages, is traceable to the difficulty of access to the holy places of Palestine, consequent on the Turkish occupation of Jerusalem and the Holy Land; these representations being designed to serve as some analogous incentive to the piety and faith of the Christian worshiper of our Lord in his passion. The number of the so-called "stations" is commonly 14, although in some places 15, and in others, as Vienna, only 11; but whatever may be their number, the subject of all is a sort of pictorial narrative of the passion. The devotional exercise itself is performed by kneeling at the several stations in succession, and reciting certain prayers at each. Forms of prayer are prescribed to those who can read. The poor and ignorant recite the Lord's Prayer and Hail, Mary! all being directed to fix their thoughts in grateful memory upon "the sufferings which each representation describes our Lord as having undergone, in atonement for the sins of mankind." Many "indulgences" are granted to those who, having duly repented of their sins, shall piously perform this exercise. Many of these stations are celebrated as works of art, especially one near Bologna.

STATISTICAL CONGRESS, INTERNATIONAL. The first congress of this character was held on the suggestion of Mr. J. C. G. Kennedy, superintendent of the U. S. census, and occurred in 1853 at Brussels. To M. Adolph Quetelet, the eminent statistician, is due the successful organization of these meetings, which were successively convened at Paris, Vienna, London, Berlin, Florence, the Hague, St. Petersburg, and Buda-Pesth. Their object has been to systematize and define the statistical work of the countries represented, and the result accomplished in this direction has been valuable and suggestive.

STATISTICS, that branch of political science which has for its object the collecting and arranging of facts bearing on the condition, social, moral, and material, of a people. The word statistics was first employed in the middle of last century by prof. Achenwall of Göttingen, who may be considered the founder of the science. The principle lying at

its foundation is, that the laws which govern nature, and more especially those which govern the moral and physical condition of mankind, are constant, and are to be discovered by the investigation and comparison of phenomena extending over a very large number of instances. Accidental diversities tend to neutralize each other, their influence diminishing as the area of investigation increases; and if that area be sufficiently extended, they so nearly disappear, that we are entitled to disregard them altogether. While the length of a single life cannot be counted on, an average of 1000 or 10,000 lives gives us a constant quantity, sufficiently near the truth to answer the purposes of insurance companies. Even the acts which are the most purely voluntary as regards individual men, have been found to be subject to laws which, in respect of the masses which make up society, are invariably in like circumstances, and discoverable.

The science of statistics has a twofold relation to political and social economy. The facts collected by the statist are the bases on which political economy rests; their application to social and economical problems is an appeal from imagination to fact. But the statist must be guided by the political economist in what direction to extend his investigations: without political economy, we should have had no statistics.

It would be difficult to give any exhaustive enumeration of the multifarious topics which may be the subject of statistical inquiries. The results of statistics have been classified as—1. Problems regarding the nature of wealth and its production and growth in a community; 2. Problems relating to inland and foreign trade; 3. Problems relating to taxation and finance; 4. Problems regarding currency, banks, and prices; 5. Problems relating to the wages and hire of labor, and the division of employments; and 6. Problems relating to the functions of the state as regards interference with the economic relations of its subjects.

The statistical section added to the British association for the advancement of science in 1833, and the London statistical society founded in 1834, have made some valuable contributions to this science, and helped to diffuse a knowledge of its principles and its importance. But while in some branches there is undoubtedly room for the labors of individuals or associations, statistics are, generally speaking, more appropriately the province of the state. The most important of the subjects with which this science is cognizant, cannot be investigated without unrestricted access to government offices, and authority to demand information; and the ordinary administration of government is continually affording opportunities for the collection of the most valuable statistical facts. For some time past, statistics have largely occupied the attention of the more enlightened governments of Europe. The statistical reports issued by the various departments of the French government deserve especial praise for the comprehensiveness of their basis, and the clearness of their arrangement. The government of Belgium has, since 1841, engaged with much diligence in statistics, and Austria and Prussia have also their statistical departments. A bureau of statistics was established in connection with the treasury department of the U. S. which issues valuable bulletins.

STATIUS, PUBLIUS PAPINIUS, Roman poet, born at Naples about 61 A.D. He was educated at Rome by his father, a distinguished grammarian and preceptor of Domitian. Young Statius soon became famous for his poetic gifts, especially for his skill in extemporaneous verse, and three times gained the prize in the Alban contests. But finally, having been vanquished in the quinquennial games, he retired with his wife Claudia to his birthplace, Naples, where he died about 96 A.D. Of his works we possess only *Silvæ*, a collection of miscellaneous poems, the *Thebæis*, an epic in 12 books, and the unfinished epic *Achillæis*.

STATU'ARY AND STATUE. See SCULPTURE.

STATUTE OF LIMITATIONS. See LIMITATION.

STATUTES, or ACTS OF PARLIAMENT, are those laws made from time to time by the legislature, which qualify and alter the common law or previous statutes. All laws may be divided into common law and statutory law, the former being unwritten, the latter being written. The theory as to the common law is, that it consists merely of ancient usages, accepted by all, of which the written exposition has perished, but which tradition has kept alive; and much of the common law necessarily consists of what has sometimes been called judge-made law—a department of law which has often been ignorantly denounced as illegal or unconstitutional, but which is a necessary part of every code, under whatever name it is disguised. The legislature of Gt. Britain consists of the queen, lords, and commons in parliament assembled, and the statutes which they pass have been likened by sir Matthew Hale to written contracts or indentures, the general public being bound, by their respective agents, as if by solemn deed. There is no legal mode of altering the previously existing law, except by a statute passed with the consent of parliament; but there are other ways of modifying the law, so far as mere details of administration are concerned—as, for example, by orders in council, by ordinances, by charters, and by by-laws issued under some inherent or statutory power belonging to corporations. The mode in which a statute is made belongs properly to the head of procedure in parliament. Statutes or acts of parliament are all founded on the theory that the legislature has an inherent right to alter all previous laws or statutes: and though sometimes great and leading statutes have been declared to be unalterable by any future parliament, this restriction is obviously utterly futile, and inconsistent with the idea of a

legislature. Statutes are usually divided, according to the number of persons affected by them, into public and private—the former applying to the whole public, the latter only to the persons named or described. There is also a subdivision of both into local and personal statutes. Statutes are also divided into declaratory, penal, or remedial, according to the nature of their object. There are certain important rules as to the interpretation of statutes, the chief business of the various courts of law and equity being to construe or interpret the statutes. A statute begins to operate from the time when it receives the royal assent, unless it state some other time for its commencement; but formerly each statute was presumed to take effect from the beginning of the session of parliament in which it passed, until the rule was changed, in 1793, by the act 33 Geo. III. c. 13. The leading rule in construing statutes is, that the words are to be taken in their ordinary grammatical sense, unless the context shows that they are used in some other sense. All other rules resolve more or less into this. There is also a well-known rule that penal statutes are to be construed less strictly than other statutes of a remedial kind. Another rule is, that a subsequent statute repeals one that is prior, either expressly or by necessary implication, if the prior one is inconsistent in substance. Though it might seem an easy task to construe or interpret what is meant by a statute, it is in practice so far from being easy that it requires a special training and long experience to arrive at an accurate mode of construction, the chief business of lawyers being to acquire this art; and one excels another solely or chiefly by virtue of the tact, skill, and accuracy of thinking which are required to do such work in perfection. All the main disputes in litigation turn chiefly on the different interpretations put by parties on statutes or contracts, both of which are construed according to precisely the same rules. Another rule applicable to statutes is, that each remains in force until it is repealed, either expressly or impliedly. So much confusion, however, has arisen out of the multiplicity of statutes, and it is so difficult for lawyers to discover what statutes have been so impliedly repealed, that of late years a process of revision and examination has been instituted by the government with a view to repeal expressly all that is obsolete and that is already only impliedly repealed, so as to reduce the bulk of the statutes, which have now grown to an inconvenient size. This task is preliminary to a codification of those statutes which remain after such revision and expurgation. American statutes are passed through congress or the state legislatures in a different method from that in usage with legislative assemblies in Europe, where great pains are taken in framing statutes, and specialists and lawyers are consulted in reference to them. In the American legislature a bill may be presented by a private member, and will then be referred to the proper committee, or a committee may introduce a bill. It must then pass through three readings, of which the first two are formal. After its passage through both houses it is engrossed, signed by the presiding officer of each house, and, if it receive the signature of the presiding officers and the executive, it becomes an “act,” and is filed in the office of the secretary of state. American statutes take effect immediately, or a certain number of days after the session, or after passage.

STAUBBACH, FALL OF, a celebrated waterfall in the southern part of the canton of Bern, Switzerland, 1 m. from the village of Lauterbrunnen, and 8 m. s. of Interlaken. It is one of the loftiest in Europe, having a descent of between 800 and 900 ft., but it often disappoints visitors, who expect a swift loud-roaring cataract, and find instead a slender stream of water, concealing the face of the precipice like a “beautiful lace veil, and imitating in its center the folds of the drapery.” Long before it reaches the bottom it is blown into a dust of silver spray, whence its name *staubbach* (dust-stream). Both Byron and Wordsworth have praised it in verse.

STAUNTON, a river in s.w. Virginia, 200 m. long, rising in Montgomery co., flowing s.e. through a gorge in the Blue Ridge mountains. It separates the counties of Franklin, Pittsylvania, and Halifax from the counties of Bedford, Campbell, and Charlotte, and unites at Clarksville with the Dan river to form the Roanoke. The upper portion is sometimes called the Roanoke. In the first 20 m. it has a fall of 1000 feet.

STAUNTON, city and co. seat of Augusta co., Va.; on the Baltimore and Ohio and the Chesapeake and Ohio railroads; 136 miles w.n.w. of Richmond. It is in the beautiful Shenandoah valley; is the seat of the Western state hospital and the state institution for the deaf, dumb, and blind; and contains the Mary Baldwin seminary, Virginia female institute, Wesleyan female institute, Staunton female seminary, Staunton military academy, the Valley training school for colored pupils, Kings Daughters' hospital, and business colleges. There are electric lights and street railroads, Gipsy Hill park, national and confederate cemeteries, waterworks, with reservoir capacity of 2,500,000 gallons, national and state banks, about 20 churches, and daily, weekly, and monthly periodicals. The chief manufactures are carriages and wagons, machinery, organs, flour, cigars, sash and blinds, and ice. Pop. '90, 6975.

STAUNTON, Howard, b 1847-4; b. Engiand received; his education at Oxford, and after extended travel settled in London, and devoted himself to literature and the game of chess. He had great skill as a player, and was enthusiastic in his researches into the obscure analysis of the game. He became the editor of the *Chess-Player's Chronicle*; also edited the chess department of the *Illustrated London News*. In 1847 he published the *Chess-Player's Handbook*; in 1849 the *Companion*; in 1851 the *Chess Tournament*; and 1860, *Chess Praxis*. He also devoted much time and study to the works of Shakespeare, of which he edited an edition in 1857-60. He also wrote *Great Schools of England*, 1865.

STAUNTON, WILLIAM, D.D.; b. England, 1803; came to America, 1818; ordained in the Protestant Episcopal church, 1834; rector of St. James's church, Roxbury, Mass., 1835-40; of St. Peter's, Morristown, N. J., 1840-47; of St. Peter's, Brooklyn, 1848; rector at Potsdam, N. Y., 1852-59. He published *Dictionary of Phrases, Subjects, and Usages of the Protestant Episcopal Church*; *Book of Chants*; *Book of Common Prayer*; *Voluntaries for the Organ*, etc. He is an authority on ecclesiastical music. He d. 1889.

STAUPITZ, JOHANN VON, descended from an ancient noble family of Misnia, but the date and place of his birth are unknown; studied theology at Tübingen; became an Augustinian monk; was called by Frederick the wise, elector of Saxony, to assist in founding the university at Wittenberg; became in 1502 its dean and professor of theology; in 1503 was made vicar-general of the Augustines for the province of Germany; procured for Luther the chair of dialectics and ethics at Wittenberg; retired from Wittenberg, 1512, to Salzburg, and became court-preacher, and in 1522 abbot of a Benedictine monastery. He aided the reformation. He wrote *De Amore Dei* and *De Fide Christiana*. D. 1524.

STAVANGER, a sea-port t. of the w. coast of Norway, in the stift of Christiansand, 35 m. n.w. from the Naze, and 100 m. s. from Bergen, on the w. side of a wide and sheltered bay of the Bukken-fiord. It is a very ancient town, with a very fine old gothic cathedral, dating from the 11th century. Stavanger has cloth-manufactories and distilleries. Ship-building is carried on, and timber and fish are exported. Pop. '91, 23,930.

STAVROPOL, a government in Russian Caucasasia, bounded on the n. by the government of Astrakhan, and by the country of the Don Cossacks; by the Caspian sea on the e.; and by the Caucasus on the south. Area 23,397 sq. m.; pop. '94, 695,366. The chief rivers are the Kuban and Terek, forming the greater part of the southern boundary, and the Kuma. In the s.w., where the soil is fertile, and produces millet and wheat, agriculture is the chief employment. Immense herds of oxen and sheep are raised. Stavropol, the capital, is on the chief highway from Europe to the Caucasus, 200 m. s.e. of Rostov. It was founded in the end of the last c. Pop. '95, 44,207.

STEALING. See LARCENY.

STEAD, WILLIAM THOMAS, journalist, b. in Northumberland, England, July 5, 1849; was apprenticed to a merchant in 1863; assistant editor of the *Pall Mall Gazette*, 1880-3, when he became editor. In 1885 he was imprisoned for three months for publishing *The Maiden Tribute of Modern Babylon*. *The Review of Reviews* was founded by him in 1890. He has published *Truth about the Navy* (1884); *Truth about Russia* (1888); *The Pope and the New Era* (1889); *If Christ came to Chicago* (1893); *The Labor War in the United States* (1894); *Satan's Invisible World* (1897), etc.

STEAM. Steam is water in the gaseous form (see **HEAT**). When dry, it is invisible and transparent, like air, and is not to be confounded with *vapor*, which is steam returned to the state of water, and thus become visible—water-dust, as it were. As steam has become the most important of all motive powers, the properties on which its action depends deserve careful consideration. The development of steam is, naturally enough, connected popularly with a high temperature, but the two things do not necessarily go together. Water (or snow, or ice) gives off vapor or steam at *every* temperature—a low temperature not preventing the formation of steam, but only decreasing its density. The only limit to this evaporation is when the air surrounding the water (or snow, etc.) is already saturated with vapor of the maximum density which the water can give off at the existing temperature. Thus water at 32° Fahr. will give off vapor of a pressure equal to 0.085 lb. per sq.in.; but if the air above it is already saturated with vapor of that density, the tendency of the particles of water to fly apart is exactly balanced by the pressure of the vapor on its surface, and no more evaporation takes place. It is a remarkable fact, that while no atmospheric pressure can prevent the water or ice passing into vapor, the previous presence in the air of vapor of the required density (even when so small as in the instance just given) entirely stops it.

Let us represent a cylinder by the letter *a*, and a piston moving steam-tight within it by *p*; and suppose that the end of the cylinder above *p* is open to the atmosphere, and that below *p* there is in the cylinder a perfect vacuum. There is then a downward pressure upon the piston equal to the whole force of the atmosphere, or about 14.7 pounds per square inch. If a little water could be introduced into the bottom of the cylinder, without admitting any air, a quantity of vapor would rise from it, and press with more or less force on the lower side of the piston, so as to sustain a portion of the weight of the atmosphere. How much vapor would rise, and how much elastic force or pressure it would exert, would depend upon the temperature of the water and the cylinder.

At 32° Fahr., as we have already said, the vapor in the space *a* would exert a pressure equal only to 0.085 lb. per sq.inch. If the temperature were raised to 80°, more vapor would rise until its pressure became about 0.5 lb. per sq.in.; at 102° the pressure would be 1 lb.; at 162°, 5 lbs.; at 193°, 10 lbs.; and so on, until at 212° Fahr. the pressure would be 14.7 lbs., or exactly equal to that of the atmosphere. When this point has been reached, it is evident that the piston will be *in equilibrio*, the pressure beneath it being exactly equal to that above. At each intermediate point the downward pressure on *p* is equal to the pressure of the atmosphere, *minus* the pressure of the steam below the piston. So far as the piston is concerned, the conditions are therefore the same as if the vacuum had been impaired by the introduction of a certain

quantity of air below p ; but there is this difference between the two cases: if the space a had been occupied by rarified air, then, by forcing the piston down, and compressing it into less space, its density would increase until its pressure became equal to or greater than that of the external air. With steam, however, if the piston were depressed, and if the temperature of the steam were preserved the same, instead of its pressure being increased, a portion of it would be liquefied, and the remainder would have the same pressure as before.

It is at 212° that water in an open vessel begins to boil; that is, the vapor rises rapidly and in volumes, being able to displace the atmosphere (see *BOILING*). In this state it is usually called *steam*; but there is no essential difference between steam at 212° and steam at 60° . The steam rising from boiling water in an open vessel is of the same temperature as the water—viz., 212° ; but notwithstanding this, it contains a great deal more heat. This heat is employed in (to use popular language) forcing asunder the molecules of the steam, and thus causing it to occupy so much greater a bulk as steam than as water. It does not make itself known by the thermometer (for which reason it is called *latent heat*), but its existence and amount are known by other means, for which see the article *HEAT*.

It is important to note, before going further, that, in speaking of the pressure of steam, we have given it in pounds per sq. in. above a perfect vacuum, or in what are called *absolute pressures*. These must be carefully distinguished from pressures (as often given) in pounds *above atmospheric pressure*. According to the method we adopt, which is the more scientific one, steam of 14.7 lbs., or one atmosphere, exactly balances the pressure of the air, and can therefore do no work against it; while, if the other nomenclature had been adopted, steam of 14.7 lbs. *above* atmospheric pressure would have been really steam of *two* atmospheres pressure. In reading on this subject the student should always make sure whether the pressures spoken of are measured above an absolute zero, or only above the atmospheric pressure, as much confusion is sure to result from any mistake on this point.

When a cubic in. of water is converted into steam at the ordinary pressure of the atmosphere, its volume is increased to 1645 cubic in.—i.e., a cubic in. of water becomes nearly a cubic ft. of steam of one atmosphere. If the steam is produced at any greater pressure, its volume will be very nearly inversely as that pressure; at two atmospheres, it would occupy about 855 cubic in.; at four atmospheres, about 457 cubic inches.

When water is boiled in an open vessel, neither the temperature of the water nor that of the steam rising from it ever rises higher than 212° , however hot the fire; the heat as it enters is carried off in a latent state in the steam. But under pressure, the temperature of both can be raised to any degree. If, when the water and steam in a , fig. 1, came to 212° , the application of heat were still continued, more steam would continue to rise, and the pressure on the under side of the piston being now greater than that of the air above it, the piston would begin to ascend; but suppose it held in the same position by force, the upward pressure of the steam would be found rapidly to increase, until it would soon require a weight of 14.7 lbs. per sq. in. to keep it down, showing that the pressure of the steam was now equal to twice that of the atmosphere, or to 29.4 lbs. per sq. inch. If at this point the temperature of the water and steam were examined, it would be found to be very nearly 250° Fahr. When the absolute pressure of the steam reached 50 lbs., its temperature would be 281° ; at 100 lbs., 328° ; at 150 lbs., 360° ; and so on.

From the numerous experiments made on this subject some very important general conclusions may be drawn. Of these, one—which will be evident from the figures just given—is, that the pressure of steam increases at a far higher rate than the temperature (doubling the temperature increases the pressure *nearly 23 times*), which shows the extreme danger of continuing to apply heat to a vessel from which the steam is not allowed to escape. The bursting force would soon become such as no vessel could resist.

Another general conclusion of great importance is, that for every temperature there is a corresponding density of steam produced. This steam contains a fixed amount of latent heat, and exerts a certain uniform pressure on every side of any vessel in which it may be contained. The following table shows the relation between these values for steam of several different temperatures:

T.	p .	H.	V.	v .
32°	0.085	1091.8	3390.0	211,536
104°	1.06	1113.7	312.8	19,519
158°	4.51	1130.1	80.02	4,993
212°	14.7	1146.6	26.36	1,645
248°	28.83	1157.5	14.0	874
293°	60.4	1171.2	6.992	436
356°	145.8	1190.4	3.057	191
401°	250.8	1204.1	1.888	115

T, Temperature in degrees Fahrenheit. This corresponds to the *sensible heat* of the steam.

p , Pressure in pounds per sq. in. of the steam at that temperature.

H, Total heat of the vapor above 32° Fahr. at that temperature (according to Regnault's hypothesis) in *thermal units*. A thermal unit (.772 foot-pounds) is the quantity of heat which will raise 1 lb. of water 1° Fahr. at or near its temperature of greatest density, 39.1° Fahr. The specific heat of water increases slowly as the temperature rises, so that 1 thermal unit will not raise 1 lb. of water quite so much as 1° at high temperature; but for the purposes of this article we need not take this into account.

V, Volume in cubic ft. occupied by 1 lb. of steam.

v , Number of times which volume of steam exceeds that of same weight of water.

The relations between temperature and pressure in the foregoing table apply only so long as the steam is in contact with the water from which it is generated. Once away from the water, its temperature may be raised without altering its pressure. Steam which has received additional heat in this way is called *superheated* steam. It approximates to the condition of a perfect gas, and therefore follows nearly what is known as Boyle's or Mariotte's law (q.v.); its volume varying always inversely as its pressure. By this law, steam which occupied 1 cubic ft. at 20 lbs. absolute pressure, would occupy 4 cubic ft. at 5 lbs., and half a cubic ft. at 40 lbs. absolute pressure.

Steam, however, as commonly used in the steam-engine, is not superheated, but used under the conditions given in the table. It is then called *saturated* steam, and differs sensibly from the condition of a perfect gas. If the pressure (p) be given in pounds per sq. in., and the product ($p\upsilon$) of pressure and volume in foot-pounds, then the formula,

$$\log. (p\upsilon) = 4.675 + .061 \log. p,^*$$

gives results accurate enough at all ordinary pressures, and can be very easily applied. The volume, instead of increasing inversely as the pressure, increases less rapidly; the difference, though not very great, is large enough to be taken into account in all calculations as to the efficiency and behavior of steam in a steam-engine.

Another fact regarding the constitution of steam requires attention; from its importance in point of economy. It would naturally be expected that it would take much more heat or fuel to convert a pound of water into steam at a higher than at a lower temperature and pressure. In reality, however, the difference is very slight. Referring back to the table, it will be seen that it requires 1146.6 units of heat to raise a pound of water from 32° to 212°, and evaporate it at that temperature; of these, 180 are expended in raising the temperature, while 1146.6—180, or 966.6 units, become latent in the steam. It only requires 1171.2 units, however (261 sensible, and 910.2 latent), to raise the water to 293°, and evaporate it at that temperature; for the latent heat falls nearly as fast as the sensible heat rises. The additional heat required is thus only a little over 2 per cent, while the pressure—which is, *ceteris paribus*, a measure of the work the steam will do—is more than quadrupled. In this way, a large increase of power in any engine may be obtained by a small additional expenditure of fuel, and consequently steam of a high pressure is now being used for all purposes, its economy and advantages being fully recognized by engineers. It was thought for a long time that the *total* heat of steam—that is, the sum of the sensible and latent heats—was constant at all temperatures; but this is not strictly the case, although the table shows that the difference, for ordinary ranges of pressure, is but trifling. See HEAT and STEAM-ENGINE.

STEAM-CARRIAGE. Very early in the history of steam-locomotion, projects were formed for running steam-carriages on common roads—not to draw a train of vehicles after them, but each carriage to have passenger-accommodation as well as steam-power. Robison suggested such a thing to Watt so far back as 1759. A French inventor, Cugnot, tried a steam-carriage at Paris in 1770, which went with so much force as to dash down a brick wall, and thereby deter other inventors. In 1782, Murdoch exhibited a model of a steam carriage; in 1784, Watt described his plans for another; and in 1786 Symington produced a model of a third. In the last-named year, too, Oliver Evans announced certain projects of the kind in the United States. In 1802, Messrs. Trevethick and Vivian patented a steam-carriage, planned on a much better principle than any that had preceded it; they adopted high-pressure steam, of which previous inventors had been afraid. The carriage was tried, but the ingenious patentees received very little encouragement, and soon turned their attention to railway matters. A long interval then passed without any new inventions in this kind of road-locomotion. When Telford and other engineers had improved the roads and highways, inventors were again induced to apply steam-power as a substitute for horse-power to road-vehicles. Bramah made a steam-carriage in 1821, on a plan patented by Julius Griffiths. Gordon invented one in 1822, which worked something like a squirrel in a cage, the engine being within a cylinder which rolled along the ground; and another in 1824, which appeared to walk upon six iron legs. Goldsworthy, Gurney, Burstall, Hill, James, Hancock, Summers, Ogle, Heaton, Church, Dance, Field, Squire, Maceroni, Scott Russell, Hills, Sir James Anderson—all invented new forms of steam-carriage between 1824 and 1841. Some of these displayed great ingenuity, and attained a speed of 10 or 12 miles an hour on common turnpike roads. Sir Charles Dance ran such a carriage between Gloucester and Cheltenham in 1831, doing the 9 miles in 55 minutes; but the opposition of local interests put him down, after he had made 400 such trips without an accident, and carried a very large number of passengers. In the same year Mr. Hancock began running his steam-carriage, called *The Infant*, regularly between London and Stratford; and some time afterward, Mr. Scott Russell ran his invention between Glasgow and Paisley. All these three were passenger-vehicles which plied for traffic on the road. In the very numerous inventions from time to time brought forward, the passengers were in some cases seated in front of the engine and boiler; in others, they were seated behind; in others, the tank for water was placed beneath the passengers' feet, while in a fourth kind there was a passenger-carriage, distinct from, but linked to, the

steam-locomotive. None of the inventions, however, attained to commercial success, so many were the difficulties which beset them.

The last quarter of a century has exhibited inventions rather for heavy traction than for passenger steam-carriages. One of the most remarkable of the latter kind is that which the earl of Caithness drove, in 1864, from Inverness to his seat near Thurso. It carried three or four persons, and ascended and descended very steep inclines without much variation of speed. As a question of profit or commercial advantage the inventors of such engines now look to their employment on common roads, for dragging heavy loads. Numerous patents have been taken out, with this view, by Boydell, Bray, Clayton, Burrell, Fowler, Aveling, R. W. Thomson, and others. In Mr. Thomson's engines, or "road-steamers," the wheels are encircled by a complete ring, or tire, of india-rubber, protected on the outside by a flexible sheath of steel plates. As engines for drawing very heavy weights these have proved the most powerful yet invented, and several of them by 1874 were constantly at work in Glasgow, dragging enormously heavy castings and boilers from the workshops of the engineers to the railways or wharves. In ordinary work, however, the road-steamers can hardly be said to have been a success. The expense connected with the renewal of the india-rubber tires, and the other parts worn by the constant jolting on common roads, has told very much against their adoption. Great endeavors have been made to design an engine suitable for use upon tramway lines laid down on common roads, but as yet without complete success. The use of steam-engines has never been permitted to any extent on city railways, with the exception of the elevated railways, and as cheaper and more satisfactory motive powers are now in use, there is little or no farther effort made to apply the steam-engine to this class of work. Numerous laws have been passed to regulate the use of locomotives upon common roads. Their regulations at first were severely restrictive, framed apparently rather to discourage than to encourage mechanical traction. Now, however, that the engines are improved, and their use more understood by the public, the popular feeling against the engines, which caused this legislation, is rapidly disappearing.

It has been a favorite idea for many years with amateur and professional mechanicians (especially the former) to make a light carriage which could be used upon ordinary roads, and which should contain a steam-engine and boiler to propel itself. In spite of innumerable attempts no permanent success has yet been obtained in this direction, notwithstanding that great progress has been made in constructing steam traction engines for common roads. The fact seems to be that, while a self-propelling steam-carriage to carry only the weight of a passenger or two *can* be made without much difficulty, its cost will be proportionately so heavy, and the trouble of keeping it in order as well as of working it, so great, that it will not succeed commercially.

The true application of steam upon common roads is in the drawing of heavy loads which would otherwise require an inconveniently large number of horses. Engines for this purpose are called *traction-engines*, and their use, notwithstanding determined, and too often ignorant opposition, seems to be yearly on the increase. Traction-engines may be divided into two classes—those with rigid tires on their wheels, and those with flexible tires. The former class is the older, and includes many ingenious but mistaken contrivances for laying down what was equivalent to an endless railway for the engine to run upon, which was at one time thought by many essential to its success. The best engines at present made with rigid tires are those of Messrs. Aveling and Porter of Rochester, which are simple and substantial in construction, and are used largely both in this country and abroad. Of the second class of traction engines those fitted with Thomson's patent india-rubber tires, and by the inventor called *road-steamers*, are the only ones that have come into anything like extended use. These tires are simply rings of india-rubber, 4 or 5 in. thick, stretched over the rim of the wheel, and protected by a flexible circle of steel shoes from being damaged by stones, etc. The advantage of flexible tires is the greater adhesion (in proportion to weight) which they give to the engine, and the saving the machinery from shocks and jars. They will doubtless be still more largely used when more lengthened experience has perfected their construction, but their great cost has hitherto much hindered their extended adoption.

STEAM-CRANE. The application of steam to the working of cranes was an obvious one, and is now universal where much hoisting work has to be done; it not only effects a great saving in labor, but causes the work to be much more quickly done, a consideration quite as important. Steam-cranes and winches are now almost invariably used on board all large steamboats, both for loading and unloading, heaving the anchor, warping the ship along by means of a cable, and other purposes. When working on a wharf, and in many other situations, it is often very convenient that the crane should be movable, so that it may go to its work in the multitude of cases where that arrangement is more convenient than the converse. For this purpose it is mounted on a plain railway truck, either of wood or iron, the truck being generally provided with clamps at the ends, by which it can be firmly secured to the rails when lifting weights. The balance construction, now universally adopted for portable cranes, was invented or suggested by the late Mr. R. W. Thomson, C.E., in 1856—its essential feature being the use of the boiler as a counterpoise to the weight to be lifted. The principal parts of a steam-crane

are: 1. The boiler, which must be of some very simple construction, as it has so frequently to be worked with excessively dirty water; 2. The framing, which is generally made of cast-iron, and supports the boiler, the engine and gear, and the jib; 3. The engine (which has almost always two small cylinders, and is fitted with reversing gear), and the pinions, wheels, drums, etc., for the hoisting and other motions; 4. The "jib" (either of wood or iron), over a pulley in the top of which the chain passes, and the purpose of which is to enable the different objects to be lifted quite clear of the ground, and deposited, when necessary, on trucks, etc.; 5. The pillar, which is firmly attached to the truck, and which, passing upward through the center of the frame, forms the pivot on which it turns round; 6. The truck itself, which supports the whole machine. If the crane is stationary, the truck, of course, is not required, the bottom of the pillar being imbedded in masonry; and for large cranes the boiler is generally made separate from the machine itself, and sometimes the engines also. A portable balance steam-crane is, when complete, fitted with the following motions: 1. Gear for hoisting, generally with two or more speeds, to be used according to the weight to be lifted; 2. Gear for raising or lowering the outer end of the jib; 3. Gear for slewing the jib (with boiler and frame attached to it); 4. Gear for propelling the truck along the rails. Steam-cranes, with forked malleable iron jibs, have been erected in recent years, which will lift a weight of 50 or 60 tons. See *illus., PULLEY, ETC.*, vol. XII.

STEAM-ENGINE. Steam-engines, in their infancy, were known as "fire" (that is, *heat*) engines; and in point of fact the older term is the more correct, because the water or steam is only used as a convenient medium through which the form of energy which we call heat is made to perform the required mechanical operations. In modern engines sufficient heat is added to the steam to raise it to a very high pressure, and the excess of this pressure over the pressure opposed to it (either atmospheric pressure or the still lower pressure in a condenser) is both the cause and measure of the work done by the engine. In earlier machines, however, the steam was raised only to atmospheric pressure, and admitted into the engine only to be at once condensed by a jet of cold water. The excess of the atmospheric pressure above the pressure in the partial vacuum caused by the condensation was then the direct cause of work. Engines of this kind are not now used; they were called *atmospheric* engines. As a source of power steam has many advantages over wind and water. It is independent of the weather, may be applied anywhere, affords a constant equable motion, and is capable of indefinite increase. Its invention, therefore, has caused a new era in the arts; and the revolution which it has brought about in industry of all kinds, as well as the influence it has had on civilization in general, and must yet have in a higher degree, are altogether incalculable.

The invention of steam as a moving power is claimed by various nations; but the first extensive employment of it, and most of the improvements made upon the steam-engine, the world indisputably owes to the English and the Americans. It would appear that as early as 1543 a Spanish captain, named Blasco de Garay, showed in the harbor of Barcelona a steamboat of his own invention. It is most likely that Blasco's engine was on the principle of the *Æolipile* of Hero, invented 130 B.C., in which steam produces rotatory motion by issuing from orifices, as water does in Barker's mill (q.v.). The preacher Mathesius, in his sermon to miners (Nuremberg, 1562), prays for a man who "raises water by fire and air," showing the early application of steam-power in Germany; and the German engineer, Sol. de Caus, in the service of the elector palatine in Heidelberg, describes, in his work, *Les Raisons des Forces Mouevantes avec Diverses Machines* (Frankf. 1615), a steam-machine, which was merely a contrivance for forcing the water contained in a copper ball through a tube by applying heat. An Italian engineer, G. Branca, invented, in 1629, a sort of steam windmill; the steam being generated in a boiler, was directed by a spout against the flat vanes of a wheel, which was thus set in motion.

In England, among the first notices we have of the idea of employing steam as a propelling force, is that contained in a small volume,* published in 1647, entitled *The Art of Gunnery*, by Nat. Nye, mathematician; in which he proposes to "charge a piece of ordnance without gunpowder," by putting water instead of powder, ramming down an air-tight plug of wood, and then the shot, and applying a fire to the breech "till it burst out suddenly." But the first successful effort was that of the marquis of Worcester. In his *Century of Inventions*, the manuscript of which dates from 1655, he describes a steam-apparatus by which he raised a column of water to the height of 40 feet. This, under the name of "fire-waterwork," appears actually to have been at work at Vauxhall in 1656. Sir Samuel Morland in 1683 submitted to Louis XIV. a project for raising water by means of steam, accompanying it with ingenious calculations and tables. The first patent for the application of steam-power to various kinds of machines was taken out in 1698 by capt. Savery. In 1699 he exhibited before the Royal society a working model of his invention. His engines were the first used to any extent in industrial operations; they seem to have been employed for some years in the drainage of mines in Cornwall and Devonshire. The essential improvement in them over the older ones was the use of a boiler separate from the vessel in which the steam did its work. One vessel, in all

* The volume is in the possession of Mr. S. Holliday, to whom we are indebted for this fact.

former engines, had served both purposes. He made use of the condensation of steam in a close vessel to produce a vacuum, and thus raise the water to a certain height, after which the elasticity of steam pressing upon its surface was made to raise it still further in a second vessel.

In all the attempts at pumping-engines hitherto made, including Savery's, the steam acted directly upon the water to be moved without any intervening part. To Dr. Papin, a celebrated Frenchman, is due the idea of the *piston*. It was first used by him in a model constructed in 1690, where the cylinder was still made to do duty also as a boiler; but in an improved steam-pump invented about 1700 he used it as a diaphragm floating on the top of the water in a separate vessel, or cylinder, and the steam, by pressing on the top of it, forced the water out of the cylinder at the other end.

The next great step in advance was made about 1705 in the "atmospheric" engine, conjointly invented by Newcomen, Cawley, and Savery. This machine held its own for nearly seventy years, and was very largely applied to mines, so that it will be worth while to give a somewhat more detailed description of it than of the others.

In this engine, which is shown in fig. 1, the previous inventions of the separate boiler, and of the cylinder with its movable steam-tight piston, are utilized, although in a new form. The "beam," which has ever since been used in pumping-engines, was used for the first time, and for the first time also the condensation of the steam was made an instantaneous process, instead of a slow and gradual one. Newcomen's engine was chiefly used, like all former steam-engines, in raising water. To one end of a beam moving on an axis I, was attached the rod, N, of the pump to be worked; to the other, the rod, M, of a piston P, moving in a cylinder C, below. The cylinder was placed over a boiler B, and was connected with it by a pipe provided with a stop-cock V, to cut off or admit the steam. Suppose the pump-rod depressed, and the piston raised to the top of the cylinder—which was effected by weights suspended at the pump-end of the beam—the steam-cock was then turned to cut off the steam, and a dash of cold water was thrown into the cylinder by turning a cock R, on a water pipe A, connected with a cistern C'. This condensed the steam in the cylinder, and caused a vacuum below the piston, which was then forced down by the pressure of the atmosphere, bringing with it the end of the beam to which it was attached, and raising the other along with the pump-rod. The cock was then turned to admit fresh steam below the piston, which was raised by the counterpoise; and thus the motion began anew. The opening and shutting of the cocks was at first performed by an

FIG. 1.

attendant, but subsequently a boy named Humphrey Potter (to save, it is said, the trouble of personal superintendence) devised a system of strings and levers by which the engine was made to work its own valves. In 1717 Henry Beighton, an F.R.S., invented a simpler and more scientific system of "hand-gear," which rendered the engine completely *self-acting*. During the latter part of the time that elapsed before Watt's discoveries changed everything, Smeaton brought Newcomen's engine to a very high degree of perfection. As the result of study and experiment he made many improvements in it, in the form of the boiler, the proportions of the cylinder, etc. It was he, too, who invented the *cataract*, a very ingenious self-acting valve arrangement, which is still universally used in Cornish engines. It is worth mentioning that, in 1725, Leupold invented an engine in which steam of a higher pressure than that of the atmosphere was employed in the cylinder, but his engine possessed defects that prevented its practical use.

The next essential improvements on the steam-engine were those of Watt, which began a new era in the history of steam-power. The first and most important improvement made by Watt was the separate condenser, patented in 1769. He had observed that the jet of cold water thrown into the cylinder to condense the steam, necessarily reduced the temperature of the cylinder so much that a great deal of the steam flowing in at each upward stroke of the piston was condensed before the cylinder got back the heat abstracted from it by the spurt of cold water used for condensing the steam in the cylinder. The loss of steam arising from this was so great that only about one-fourth of what was admitted into the cylinder was actually available as motive-power. Watt, therefore, provided a separate vessel in which to condense the steam, and which could

be kept constantly in a state of vacuum, without the loss which arose when the cylinder itself was used as a condenser. This device, which now looks simple enough, was the greatest of Watt's inventions, and forms the foundation of his fame. His genius was such that in a few years he changed the steam-engine from a clumsy, wasteful, almost impracticable machine into a machine practically the same as we now have. The principal improvements since his time have been either in matters relating to the boiler; in details of construction consequent on our increased facilities, improved machinery, and greater knowledge of the strength of materials; in the enlarged application of his principle of expansive working; or in the application of the steam-engine to the propulsion of carriages and vessels. His principal inventions were: 1. The condensation of steam in a vessel separate from the cylinder, so as to avoid the cooling of the latter; 2. The use of a pump, called an "air-pump," to withdraw the condensed water, and mixed steam and air, from the condenser; 3. To surround the cylinder either with a steam-jacket or with some non-conducting body, in order to prevent radiation of heat (these three, with others, were included in the specification of 1769); 4. To use the steam expansively in the way explained further on in this article (this was invented before 1769, but not published till 1782); and 5. The now universally used double-acting engine, and the conversion of the reciprocating motion of the beam into a rotary motion by means of a crank (both these were invented before 1778, the engine being patented in 1782, but the crank having before that date been pirated and patented by another). In 1784 Watt also patented and published his parallel motion, throttle-valve, governor, and indicator; all four of which are in substance still used.

It would be inconsistent with our limits to enter into any description of the constructive details of steam-engines; we can only afford to give a general notion of the way in which the motion is originated, and to explain the chief principles on which the motive-power and economy of engines depend. We shall consider the latter first, and may say that the article STEAM should be read as an introduction to what follows, as we must assume a familiarity with the statements there made.

The common mode of employing steam in an engine is by causing it to press alternately on the two surfaces of

Fig. 2.

a movable diaphragm or piston inclosed in a fixed, steam-tight, cylindrical box. In fig. 2, A is the piston, and B a section of the box. The piston, by means of a rod E, passing through the end of the box, is made to communicate motion to the rest of the machinery. The steam is first admitted to one end of the cylinder through an opening D, and forces the piston along to the other end. The current of steam from the boiler is then allowed to pass into the other end of the cylinder through the opening C, and forces the piston back again to its original position, and so on. But it is obvious that while this return-motion is going on, the steam previously admitted at D

must be allowed some exit, or the piston could not be forced back. The manner of this exit constitutes the difference between the two principal classes of engines, according as the steam is allowed simply to rush out into the atmosphere, or is conducted into a separate vessel, and there "condensed."

The simplest way in which steam can be used in a cylinder is at the same time the most wasteful. It consists in filling each end of the cylinder alternately full of steam direct from the boiler, and having the full boiler pressure, and thus forcing the piston along in exactly the same way as that in which it would have to be forced were water the fluid used instead of steam. We have said this is wasteful; let us examine the reasons. If we imagine the cylinder to have a capacity of 7 cubic ft., then, if it be filled entirely with steam from the boiler at 60 lbs. pressure, it will contain just one pound-weight of steam.* The total heat in this pound of steam, as given in the table, is equivalent to 1171 thermal units.† When the piston has reached the end of its stroke, the steam contained in the cylinder is thus in itself a great storehouse of work, for each of these thermal units is equivalent to 772 "foot-pounds" of mechanical energy. But instead of utilizing this force, at the moment when the cylinder is full of steam the one opening is put into communication with the boiler, the other opening with the atmosphere, and the steam immediately rushes out of the cylinder, and dissipates its contained energy through the air.

It must be remembered that although the steam, when allowed to go into the atmosphere, is immediately reduced to the pressure corresponding to the temperature of the air (which in ordinary cases would be only a fraction of a pound per square inch), still the full pressure of the atmosphere itself will always be acting on the back of the piston during its stroke; and that therefore, to find the force with which the piston is being pushed along, we must subtract that pressure from the steam-pressure. On the one side of the piston will be the atmosphere with its uniform pressure of nearly 15 lbs. per square

* These figures are near approximations only, as will be seen from the table in article STEAM.

† A "thermal unit" is the quantity of heat necessary to raise, through 1° Fahr., the temperature of a pound of water at its temperature of max. density—viz., 39.1° Fahr., and may be considered, without much error, as the quantity of heat necessary to raise a pound of water 1° Fahr., at any place on the thermometric scale.

inch, and on the other side the steam pressure of 60 pounds. The effective pressure thus will be 60—15, or 45 lbs. per square inch only.

Let us now consider the somewhat more economical case of an engine in which the steam is first used as described above, but afterward, instead of being allowed to pass into the atmosphere, is conducted through a pipe into a closed vessel, and there condensed. The process commonly called condensation, and associated with the idea of liquefaction, consists in essence merely of the subtraction from steam of a portion of its sensible heat. This reduction of temperature has a double effect on the steam—first, the liquefaction of a part of it; and then, the reduction of the rest to the pressure corresponding to the reduced temperature. (It will be remembered that steam exists at *all* temperatures.) It is not possible to do one of these things without the other, and this fact lies at the bottom of a correct conception of what is called by engineers a “vacuum.” What is commonly called “vacuum” simply means pressure less than the atmospheric pressure; and, in the case of steam-engines, a vacuum generally implies a pressure of between 2 and 4 lbs. per square inch—that is, from a seventh to a fourth of the ordinary pressure of the air. The most common way of condensing steam is by bringing it into contact either with a jet of cold water, or with surfaces kept continually cool by a current of water. In either case, directly the steam is brought into contact with the water, or cooling surface, it transfers to it the larger portion of its sensible heat. During this process, the greater part of the steam is liquefied, and the remainder retains only such a pressure as corresponds to its greatly reduced temperature.

The advantages possessed by a condensing over a non-condensing engine will now be obvious. When the piston is being forced from one end of the cylinder by steam entering through the other, the force on the back of the piston resisting its motion in that direction, instead of being equal to the pressure of the atmosphere, is only the pressure of the steam in the condenser, or about 1 lb. per square inch. The net effective force is therefore 60—1, or 59 lbs., instead of 60—15, or 45 pounds. In actual practice these figures would be modified, because, from various causes, such a low back pressure as 1 or 15 lbs. above zero (in condensing and non-condensing engines respectively) is never obtained, but the principle remains the same.

We have supposed that our cylinder, when full of steam, contained just 1 pound-weight at 60 lbs. pressure. Let us now find out how much useful work this pound of steam has done for us, and we will then show how the same weight may be made to do a great deal more, by utilizing more of its great store of heat. Let us suppose that the area of the cylinder is 2 sq. ft., while its length (the stroke of the piston) is $3\frac{1}{2}$ feet. It will thus have a capacity of 7 cubic ft., as before assumed. In the first case described, we should have a pressure of 45 lbs. per square inch exerted on an area of 288 sq. in., through a distance of $3\frac{1}{2}$ feet. This is equal to 45,360 foot-pounds of work. In the second case, we have a pressure of 59 lbs. per square inch on the same area, and through the same distance. This is equal to 59,472 foot-pounds of work, or about $\frac{1}{5}$ of the total heat supplied by the fuel.* We may now proceed to examine the way in which the same weight of steam, generated by the consumption of an identical weight of fuel, may be made to perform many times more work by “working expansively.”

One of the properties possessed by steam, in common with all other gases, is a tendency to expand indefinitely. In article STEAM we mentioned and illustrated the fact that its pressure varied nearly inversely as its volume. For simplicity's sake we shall here assume that steam is a perfect gas, and follows Boyle's law, the pressure varying *exactly* inversely as the volume. We shall now describe the way in which this expansibility of steam is taken advantage of by the engineer. If we have a cylinder of the same area as before, but of twice the length, but only intend to admit 1 lb. of steam into it at a time, it will be necessary, when the piston has traveled $3\frac{1}{2}$ ft. of its stroke, to shut the entrance valve, so as to prevent more steam entering; this is called “cutting off” the steam. The piston, however, still continues its motion in the same direction as before, propelled by the internal separative energy among the particles of steam. But as it is pressed forward, the space occupied by the steam is always increasing, and its pressure always decreasing in proportion, until at length, when the piston has reached the end of its stroke, the steam occupies exactly double its original volume—viz., 14 cubic ft., and is reduced in pressure to half its original pressure—viz., to 30 lbs. per square inch. We have thus, during the first half of the stroke, a constant pressure on the piston of 60 lbs. per square inch, and during the second half a pressure gradually decreasing from 60 to 30 pounds. The *mean* pressure during this second half of the stroke will be found on calculation to be almost exactly 40 pounds. Let us now, in the same way as before, see what work we have been able to get out of our pound of steam by expanding it in this way. In the first half of the stroke we have 59,472 foot-pounds of work exactly as before, and then we have in addition a mean pressure of 40—1, or 39 lbs. per square inch, exerted over 288 sq. in. for a distance of $3\frac{1}{2}$ feet. This equals 39,312 foot-pounds, making a total of 98,784 foot-pounds of work obtained from the steam which only gave us 59,472 before. The economy of working expansively, how-

* For simplicity's sake, we have here assumed that the water in the boiler has to be raised from 33° to 292°, and evaporated at that temperature. If the water were supplied at 212°, then the work done would be about $\frac{1}{15}$ instead of $\frac{1}{5}$ of the total heat.

ever, goes much further than this. If the cylinder had been four times its original length, and the steam had been cut off at the same point as before (which would then be quarter instead of half stroke), we should have obtained from the 1 lb. of steam 144,345 foot-pounds of work. If we had gone still further, and expanded the pound of steam into eight times its original volume, we should have obtained no less than 179,984 foot-pounds of work, which is more than three times as much as at first.* All modern engines are worked more or less on this principle of expansion, and the general tendency seems to be every year to adopt higher initial pressures, and larger ratios of expansion.

Having thus briefly sketched the history of the steam-engine, and the theory of its action, we may now proceed to some consideration of its mechanism. Fig. 3 represents Watt's "double-acting" condensing engine, which we have already mentioned. By "double-acting engine" we mean an engine such as was sketched in fig. 2, in which the steam acts on both sides of the piston instead of only on one, as in Newcomen's engine. Watt's engine, though not of the form now generally used, contains all the parts now considered essential; and we may therefore describe it before saying anything about these parts in detail. The steam from the boiler passes direct to the valve-chest *v*, which is simply a long box attached to the cylinder *a*. In this chest are placed valves, which

FIG. 3.

are so regulated as to open communication between the boiler, cylinder, and condenser, in such a way that when the top of the cylinder is open to the boiler, the bottom communicates with the condenser, and *vice versa*. When the steam has done its work, it passes out through the bent pipe into the condenser *f*, where it is met by a jet of water (not shown in the engraving), and condensed, as before explained. *g* is a pump called the air-pump, which continually draws away the contents of the condenser, and discharges them into a cistern *h*, called the hot-well. A small force-pump, *j*, draws part of the water from this cistern, and sends it back again to the boiler, there to be reconverted into steam, while the rest of the water is allowed to run to waste. A suction-pump *k*, supplies water to the large tank round the condenser, and also for the condensing jet. Inside the cylinder are the piston and the rod (called the piston-rod) connecting it with the beam *bb*. In Newcomen's engine, the rod had only to pull the beam down and not to push it up; it could, therefore, be connected to it by a chain, as shown in fig. 1. In the double-acting engine, the piston-rod is required both to pull and to push the beam, so that the chain is no longer admissible. It is obvious that as the head of the rod must move in a straight line, while every point in the beam describes an arc of a circle, the two cannot be rigidly connected. Watt invented the arrangement of rods shown in fig. 3, by which the piston-rod head is always guided in a straight line, while the end of the beam is left free to pursue its own course. This is called a "parallel motion."

* In actual working, owing to various causes—such as imperfect action of the valves, radiation from the cylinder, bad vacuum, etc.—the work obtained from the steam is not more than .65 to .75 of that given in this paragraph.

The end of the beam furthest from the cylinder is connected by a rod *cc*, called a connecting-rod, to the crank *l*, which is firmly fixed on the shaft; and by this means the reciprocating motion of the beam is converted into the rotary motion of the "crank-shaft" *r*. The governor *m*, and the fly-wheel *ee*, will be explained further on.

The cylinder and its piston are both made of cast-iron. The former is very accurately bored in a lathe, and ought always to be covered outside with non-conducting material to prevent radiation of heat. It is frequently inclosed in another cylinder, and the annular space, or "jacket" between them filled with steam from the boiler, principally with the object of preventing liquefaction in the cylinder, which is fatal to economical working. The openings for the entrance or discharge of the steam are called *ports*.

The valve or valves which regulate the admission of steam to the cylinder vary very much in construction and design. In ordinary engines one valve, called a *slide-valve*, does the whole work for each cylinder in a way which we shall explain by the aid of fig. 4. This figure shows the valve in two positions—namely, those corresponding to the times when the piston is at the middle of its stroke, going in the two different directions—*c* and *d* are the ports; *b* is the "exhaust port," or opening through which the steam passes to the condenser; and *a* is the slide-valve working inside the steam-chest (not shown). The sketch to the left shows the position of the valve when the piston is moving upward. The steam enters the cylinder through *d*, as shown by the arrows, while the steam in the other end is free to rush out by *c*, under the valve, and through *b* into the condenser. By the time the piston has reached the same position, going in the opposite direction, the valve is in the position shown in the right-hand sketch, and the motion of the steam is exactly reversed. When it is desired to "cut off" the steam earlier than half-stroke, a separate valve, called an *expansion valve* (of which there are innumerable varieties) is generally used. The rod to which the piston is attached is called the *piston-rod*, and the rod which actually drives the crank the *connecting-rod*. In Watt's engine, and similar machines, these are connected to opposite ends of a *beam*, but in the common type of engine the two rods are directly attached.

FIG. 4.

The *fly-wheel* is a large wheel fixed on the crank shaft, and having a very heavy rim. As it revolves, this contains, *stored up* in itself, a great quantity of energy, and so equalizes the motion of the shaft, and, by *restoring* some of the energy, enables the engine to pass the "dead-points," or points at which the connecting-rod and crank are in a line.

The *condenser* is simply a cast-iron box of any convenient shape. The water for condensing the steam is introduced into it in a jet, or surrounds coiled pipes, through which the steam passes, so as to condense it almost instantaneously.

The *governor* is an ingenious application by Watt of mechanism long used in water-mills. Its object is to make the engine to a great extent regulate its own speed, so that it shall neither be pulled up altogether by a sudden increase of load, nor "race" when any part of its load is suddenly removed. It consists essentially of a spindle or upright rod, with a pulley, by which it is caused to revolve, fixed on it. Two levers are pivoted on a pin near the top of the spindle, and at the lower end of each is fixed a heavy cast-iron ball. When the engine is running at its proper speed, the balls revolve with the spindle in the position shown; but if that speed be increased, the centrifugal force causes them to fly outward, and consequently upward; and conversely, if it be decreased, they fall downward toward the center. At the upper end of the spindle is a system of levers, by which the raising of the balls tends to close, and their lowering to open, the *throttle valve*. This valve is simply a disk of metal placed in the steam-pipe near the cylinder. The further, therefore, it is opened, the greater the amount of steam admitted to the cylinder, and *vice versa*, and so the tendency of the engine to alter its speed arising from causes extraneous to itself, is just balanced by the alteration made in the amount of steam admitted through the throttle-valve. In order that economy as well as regularity of working may be attained, the governor should, however, be so arranged as to control the "cut-off" instead of throttling the steam.

The "Cornish" engine, so called from the fact that it is principally used in the Cornish mines, resembles Watt's engine in general appearance. Like Newcomen's engine, it is used exclusively for pumping, and has no rotary motion, and it is virtually single-acting; but unlike his, the steam pressure, and not that of the atmosphere, actually does the work. It is not easy to say why Cornish engines have remained so long in their original form. They are economical of fuel, owing to the great expansion used, but the same expansion could also be used with many other forms of engine. They are very costly, and extremely heavy and unwieldy, and it seems probable that it is only prejudice which stands in the way of their being superseded by small engines running at high speeds, which would do the same work as economically, and with a much smaller outlay in first cost.

Engines in which the piston-rod and connecting-rod are directly attached are called

direct-acting engines, of which the horizontal engine is the most common type, and for all ordinary purposes is rapidly superseding every other form of stationary engine. It possesses the merits of having great simplicity and few working parts, and of all these parts being easily accessible to the engine-driver; and at the same time any required degree of economical working can be obtained in it as well as in any other form. It was for a long time only used non-condensing, but is made so that it can be used with a condenser or not as desired.

Two other forms of direct-acting engines have been much used in their day, but are now being rapidly abandoned except under special circumstances; these are called respectively the "oscillating" and the "trunk" engine. In the former (which has rarely been used except for marine engines), the crank-shaft is above the cylinder, the piston-rod head is attached to the crank-pin, and the connecting-rod is dispensed with by allowing the cylinder to oscillate on large hollow centers called *trunnions*, and so to adapt itself to the various positions of the crank-pin. In the "trunk" engine, the piston-rod becomes a hollow cylinder or *trunk*, large enough to allow the connecting-rod to vibrate inside it. The latter is then attached at one end to the crank-pin as usual, and at the other to a pin fixed in the piston.

An immense amount of ingenuity has been expended in devising engines in which the rotary motion of the shaft is obtained *directly* from the piston without the intervention of reciprocating parts. These machines are called *rotary engines*; they have never come into general use, and most of them have been defective in construction, as well as founded on a dynamical misconception.

In *locomotive engines* it is necessary that the whole machinery should be compressed into the smallest possible bulk, and this necessity is the cause of their principal peculiarities. The engine itself is much the same as an ordinary horizontal engine, and has

FIG. 5.

two cylinders placed side by side near the front of the locomotive. These cylinders are sometimes placed inside the main framing, which runs the whole length of the engine, and sometimes outside it, each plan having certain advantages. Fig. 5 is an outline section of an "inside cylinder" freight locomotive belonging to the Midland railway company. At the back of the locomotive is the fire-box *a* the bottom of which is formed by the grate *b*. Fuel is introduced by the door *c*. The fire-box is inclosed in a casing *d*, and the space between is filled with water. This space communicates freely with the barrel *ee* of the boiler, a long wrought-iron cylinder. From the back of the fire-box numerous small tubes traverse the boiler (through the water) to the smoke-box *f*, and conduct the products of combustion to the chimney *g*. The steam-pipe *k* is led away from near the top of the dome *h*, and fitted with a regulator valve *l*. At *m* are a pair of spring safety-valves. Both cylinders discharge their steam through the vertical blast-pipe *p*, and by this means a sufficient draught is caused, notwithstanding the small height of the chimney. The "compound" system explained below is gradually being applied to locomotives, and gives marked economy. The high-pressure cylinder is placed on one side of the locomotive and the low-pressure cylinder on the other.

In all *marine engines*, except the very smallest, two cylinders are used, working cranks at right angles to each other, so as to equalize the motion as far as possible, it being almost impossible to use a fly-wheel of sufficient weight for that purpose on board ship. In vessels of war, where it is essential that all the machinery should be kept below the water-line, horizontal engines are used, often of the "trunk" type. In merchant vessels, however, and in all cases where there is no necessity for the machinery being kept low down in the ship, the form known as the "steam-hammer" engine, or

some modification or it, is now almost universally adopted. These engines derive their name from their resemblance (in their earlier designs) to Mr. Nasmyth's steam-hammer, the form of which seems to have suggested their arrangement. They are direct acting, but the cylinders are inverted, and placed right above the propeller shaft.

The two greatest improvements in the modern steam-engine—the *surface condenser* and the *compound engine*—have been brought to perfection chiefly in connection with marine engines, and we may therefore mention them here. In the surface-condenser, the steam is condensed by contact with the surface of a great number of small tubes, through which a current of cold sea water is kept constantly flowing. By this means the condensing water and the condensed are kept separate, the former being returned to the sea, and the latter only sent into the hot-well. The boiler, therefore, is continually fed with distilled water, and the wasteful process of “blowing off,” to get rid of the unvaporizable matter which would otherwise be deposited in the boiler, is rendered unnecessary.

In “compound” engines, the two cylinders are of unequal size—the larger, called the low pressure cylinder, having from three to four times the capacity of the smaller or high-pressure cylinder. The steam from the boiler is admitted into the latter in the usual way, and cut off generally at from $\frac{2}{3}$ to $\frac{3}{4}$ of the stroke; and after doing its work there, it is conducted to the large cylinder, where its reduced pressure, by acting on an increased area, does as much work as in the other cylinder, and thence to the condenser. This system of engine has several notable advantages—among which are that the internal stresses are more uniform than in ordinary engines; that leakage past the piston becomes of less importance; and that for any given *large* measure of expansion, the mechanism of the engine is much more simple and less liable to get out of order than for the same degree of expansion carried out independently in two cylinders. The next step was the triple-expansion engine, in which three cylinders are used, through which the steam expands successively. The most modern marine engines are of this class.

The Work Done by Steam-engines.—This is estimated in two ways—as *horse-power*, and as *duty*, and the first expression includes two things—nominal and indicated horse power. Thirty-three thousand foot-pounds of work done per minute is called one horse-power, this being considered by Watt as the maximum force which a strong horse could exert. The *nominal* horse-power of an engine has long ceased to be any expression of the actual power it exerts; it is only used as a kind of commercial standard (a very deficient one) for the sale and purchase of engines, and is generally made to depend entirely on the diameter of the cylinder.

The indicated horse-power is the most useful measure we have of the work done by an engine. It expresses, however, the total work done by the steam on the piston, and does not show at all what proportion of that work has to be expended in overcoming the friction of the engine itself. It is ascertained by the use of a little machine called an “indicator,” devised by Watt, and since his time greatly improved, especially by Mr. Richards.

By taking the *mean* pressure per square inch on the piston throughout the stroke (deduced from the indicator card), and multiplying it by the area of the piston, and by the number of feet passed through by it in a minute, we should find the number of foot-pounds of work done by the engine per minute; and this, divided by 33,000, would give the indicated horse-power.

“Duty” is a measure of power used only for pumping engines, and differs from horse-power in being entirely independent of time. It is the number of foot-pounds of net work resulting from the consumption of a given quantity of coal, usually either a bushel of 94 lbs. or a hundred weight. At the beginning of this century the maximum duty that had been attained by any Cornish engine was 20 millions of foot-pounds per cwt. of coal, but six times that duty has since been occasionally obtained. In these engines, it is the actual net work done which is taken into account; the duty would be 20 or 25 per cent. greater if the total load on the steam-piston had been considered instead.

For engines whose power can only be measured by the indicator, the standard of economy is the number of lbs. of fuel used per hour per indicated horse-power. In factories where “dross” is used as fuel, with horizontal engines and Cornish boilers, and where no means are taken to insure economy, we have known 15 to 20 lbs. of fuel burned per indicated horse-power per hour. In marine engines and other cases where the best coal only is used, and where high pressures, surface condensation, and compound cylinders are employed, the consumption of fuel is often as low as 2 pounds.

The theory of a “perfect heat-engine,” which should return in mechanical work (see **FORCE**) the greatest possible amount of the heat supplied to it, is considered under **THERMODYNAMICS**. For other points, see articles **BOILER**, **SAFETY VALVE**, and **SCREW PROPELLER**, as well as **STEAM**. See *A Manual of the Steam Engine* by R. H. Thurston (1892).

STEAM-HAMMER, THE, has doubtlessly contributed more than any other mechanical invention of modern times in developing the wonderful resources of the iron trade, and is still looked upon as a marvel of engineering skill and ability. The first idea of a steam-hammer appears to belong to James Watt, the great father of engineers, and was patented by him in 1784. In 1806, a William Deverell, described as “an engineer of

Surry," also took out a patent for a steam-hammer; but in neither case does it appear that steam-hammers were actually constructed. From this time till 1839, the idea seems to have been entirely lost sight of, when it was again taken up by Mr. James Nasmyth, of the Bridgewater foundry, Patricroft, near Manchester, as the result of an application made to him by Mr. Francis Humphreys, engineer to the Great Western Steamship company, who had been unable to induce any forge-master to undertake the forgings required for the paddle-shafts of the *Great Britain* steamship, then in course of construction. Mr. Nasmyth sent a sketch of his hammer plan to Mr. Humphreys, who, along with Mr. Brunel and others, heartily approved of the scheme, but in consequence of an alteration being made in the propelling arrangement of the great ship, the paddle-shaft was not required, and the hammer was not then constructed. The scheme was offered to many of the large forge-masters and engineers; but while all seemed to admire the idea, they failed to appreciate its value and importance, and the hammer remained a mere sketch in Mr. Nasmyth's "scheme-book" till 1842, when, in June of that year, Mr. Nasmyth secured a patent for his invention, and the first steam-hammer was made in accordance with his plan at the Bridgewater foundry early in 1843; but although considered by some as an improvement upon the old "helves" hitherto used for forging purposes, it was very far from being a perfect or even a marketable tool. The hammer was worked by means of an ordinary slide-valve and a long lever, requiring great labor and constant attention in order to give the blow required; so that some contrivance was necessary, capable of adjustment, in order to have complete command over the power of the blow, and that, the instant the blow was struck, the block should rise again, so that not only no loss of time should ensue, but that the heat in the mass of iron on the anvil might not be reduced or carried off by the cold face of the block. The peculiar difficulty of securing a true automatic arrangement will be seen when it is considered that the instant of percussion must vary with almost every blow that is struck; for the piece on the anvil becomes thinner and thinner by each succeeding blow, and in flat bars a blow is first given on the flat side, and then on the edge, the difference in the fall of the hammer in the two cases being oftentimes several inches; and further, that the hammer must be under perfect control at all times.

Mr. Nasmyth, after many and protracted trials, failed to produce the motion required, and, as a consequence, the whole hammer scheme was on the point of being abandoned. In this dilemma, and during Mr. Nasmyth's absence from the works, his partner, Mr. Gaskell, applied to their engineering manager, Mr. Robert Wilson, who afterward became managing partner and successor to Mr. Nasmyth, to endeavor to solve the problem which had hitherto baffled the skill of Mr. Nasymth. Mr. Wilson took the matter in hand, and in little more than a week, a motion was invented and attached to a hammer upon which former experiments had been made, and was at once found to answer most admirably every condition required. Under the influence of this very beautiful mechanical motion every variety of blow could be given, from the gentlest tap to the heaviest blow within the compass of the hammer, and that, too, perfectly self-acting in every respect, the long lever and the hard work before referred to being now entirely banished. By simply altering the position of the tappet lever by means of two screws, a blow of the exact force required could be produced and continued so long as steam was supplied. So completely was the hammer now under control, that it became a favorite amusement to place a wine-glass containing an egg upon the anvil, and let the block descend upon it with its quick motion; and so nice was its adjustment, and so delicate its mechanism, that the great block, weighing perhaps several tons, could be heard playing tap, tap, upon the egg without even cracking the shell, when, at a signal to the man in charge, down would come the great mass, and the egg and glass would be apparently, as Walter Savage Landor has it, "blasted into space." On Aug. 18, 1843, the first hammer was delivered to Messrs. Hird, Dawson, and Hardy of the Low Moor iron works, near Bradford, Yorkshire, and gave such satisfaction, that orders for this remarkable tool began to flow in from all parts of the country. The hammer remained in this condition, with the exception of a few minor details, from 1843 to 1853, when Mr. Wilson (who in the interim had removed to the Low Moor iron-works) invented, patented, and applied to the hammers at Low Moor and elsewhere what is called the "circular balanced valve." The *Practical Mechanic's Journal* for 1855, vol. viii., p. 174, in an article on this invention, says: "The wonders of Mr. Nasmyth's invention, the steam-hammer, have just received new luster at the hands of Mr. Wilson, to whom belongs a large portion of the credit attaching to the early practical development of the beautiful automatic action of this invaluable tool. The special feature which Mr. Wilson has introduced is his balanced-pressure cylindrical valve, several modifications of which we noticed in our pages of June and July last year. Hammers divested of all self-acting apparatus whatever, and fitted merely with a hand-gear valve of this kind, exhibit an immensely improved action, enabling the workman to obtain the exact kind of blow he wants under all circumstances. This adjustment of the hammering force is attained just as effectually as with the simple hand-hammer of the smith, one stroke giving perhaps a mere touching tap, and the next a blow of the highest intensity."

In July, 1856, Mr. Wilson returned to the Bridgewater foundry as managing partner in the firm of James Nasmyth and company, and in September following obtained a pa-

tent for a *balanced slide-valve*, and at once arranged to apply his invention to all hammers subsequently to be made there, which arrangement continues in operation to the present time. His balanced slide-valve, by a most ingenious arrangement, allows the valve, as it were, to float in an atmosphere of steam pressing equally upon it on every side, entirely doing away with all superincumbent pressure upon the *valve*, no matter what the pressure in the *boiler* may be. The great advantage of this invention will be apparent when it is stated that hammers are now made of such a size, that, if the valve were not balanced, a small steam-engine would be required to move it.

In June, 1861, Mr. Wilson patented and introduced another very important improvement, popularly known as the *double-acting hand-gear motion*. By this arrangement, the steam is admitted as before to *raise* the piston, and when it has attained the required elevation, and at the very moment when about to descend, by slightly increasing the travel of the hand-lever (more than when working single-acting), the steam is admitted into the cylinder *above* the piston, which accelerates and increases the intensity of the falling blow and the consequent capacity of the hammer; so much so, that that which had hitherto been described as a *five-ton* hammer is by this double-action arrangement increased to at least a $12\frac{1}{2}$ or 15 ton one.

In 1862, Mr. Wilson designed and constructed a small hammer suitable for tilting steel, fitted with the balance-valve, double acting, and with an entirely new self-acting motion (much less complicated than the original one) capable of striking *five hundred* blows per minute. There are many patents for this kind of hammer, which is now very largely used in the forging of steel.

The largest steam-hammer ever constructed is at the steel-works at Bethlehem, Pa. The cylinder is 76 inches in diameter, and it has a stroke of $16\frac{1}{2}$ feet. The weight of the piston, piston-rod, and trip together is 125 tons, and the anvil foundation is composed of 22 blocks of iron, each weighing 70 tons. There are 1800 tons of iron and steel in the foundation of this machine. Another large steam-hammer is at Perm (a town in the n.e. of Russia), and is used for the manufacture of large cast-steel guns. It is a 50-ton hammer, made double-acting in the way above mentioned, so as to be equal to a 100-ton single-acting one. Its anvil-block is the largest casting ever made, weighing considerably more than 500 tons.

STEAM-HEATING. See WARMING AND VENTILATION.

STEAM-NAVIGATION. When once steam was known as a moving power, its application to navigation was obvious enough: it was even to this purpose that the first attempt was made to apply it at all—that of Blasco de Garay—namely, in the harbor of Barcelona in 1543. See STEAM-ENGINE. The only surprising thing is, that 30 years should have elapsed—between 1777, when the steam-engine had become in Watt's hands an efficient power for other purposes, and 1807, the date of Fulton's first voyage—before a really serviceable steam-vessel was produced. The connecting link seems to be the use of revolving-paddles instead of oars. Wheel-boats propelled by oxen, horses, or men were known to the Romans, and were used for ferry-boats in modern times. Some experiments with this mode of propulsion made by Mr. Miller of Edinburgh, suggested to his friend Mr. Taylor the application of steam as the moving power, and led to the most decided step in the discovery of steam-navigation previous to the final success of Fulton.

As early as 1736 Jonathan Hulls had taken out a patent for a tow-boat to be propelled by a paddle-wheel set in motion by a sort of steam-engine. The project appears never to have been executed. Besides some experiments on the Seine by comte d'Auxiron in 1774, and Perier in 1775, the marquis de Jouffroy constructed a steamboat of considerable size in 1782 which navigated the Saône for some time; it was deficient, however, in power. In America experiments began to be made about 1783 by Fitch and Rumsey. Fitch launched a paddle steamboat in 1788 which moved at the rate of 4 m. an hour; but before proceeding far the boiler burst. Rumsey proposed to propel the vessel by making a stream of water issue with force from the stern; his attempt failed.

The next important experiment was the one above alluded to, by Messrs. Miller and Taylor. It took place on a small lake on Mr. Miller's estate of Dalswinton in Dumfriesshire. A small engine having 4-in. cylinders of brass was prepared, under the superintendence of Mr. Taylor, tutor in Mr. Miller's family, and Mr. Symington, an ingenious mechanic, and fitted on board a double boat, with a paddle-wheel in the interspace. The trial took place amid a concourse of hundreds on Oct. 14, 1788, and with perfect success. Next year Mr. Miller had larger engines fitted into a vessel, and tried on the Forth and Clyde canal, when the vessel moved at the rate of 7 m. an hour. Partly from caprice, partly from derangement of his affairs, Mr. Miller was diverted from pursuing the matter further. But in 1801 Mr. Symington took out a patent for the construction of steamboats, and in 1803 built the *Charlotte Dundas*, to tow vessels on the Forth and Clyde canal. The success seems to have been complete, excepting in one respect, that the agitation of the water by the paddles was found to wash down the banks in an alarming manner. The use of the vessel was therefore given up, and it lay at *Lock Sixteen* for many years.

In the meanwhile, attempts had been making at steam-navigation in America by Stevens, Livingston, and others. Robert Fulton, another American, had thought of

steam as a motive-power for vessels as early as 1793. Traveling into Scotland he visited the unfortunate *Charlotte Dundas*, and obtained drawings of the machinery. Returning to America with one of Boulton and Watt's engines of 20 horse-power, he, in conjunction with Livingston, built a vessel called the *Clermont*, at New York, and in 1807 made the first really successful voyage by steam from New York to Albany, up the Hudson. The vessel sailed 110 m. in 24 hours, against stream and wind. Fulton has thus indisputably the honor of having first proved the practical utility of steam-navigation. Yet nothing but perseverance seems to have been wanting to crown the experiments of Miller, Taylor, and Symington with equal success. Four years later, 1811, Henry Bell of Glasgow, who had witnessed the experiments on the canal in 1789, and had accompanied Fulton on his visit to the *Charlotte Dundas*, started a steamboat, the *Comet*, on the Clyde, and was thus the father of steam navigation in Britain. The first American steamer to cross the ocean was the *Savannah*, which sailed from Savannah, Ga., May 25, 1819, and reached Liverpool June 20.

In 1815 a steamboat made a passage from Glasgow to London, and in 1818 one plied from New York to New Orleans; it was not till 1820 that steam-packets were established between Holyhead and Dublin. 1838 was a memorable year in the history of steam-navigation. The steamer *Sirius* sailed from Cork on April 4, the *Great Western* from Bristol on the 8th of the same month; both arrived at New York on the 23d, the *Sirius* being only twelve or fifteen hours before the other. The passage is now often made from New York to Queenstown in less than six days. Steam-vessels are now to be found on all seas and lakes and navigable streams. War-steamers have taken the place of the old ships of the line; and except for the transport of heavy goods to long distances, steam bids fair to supersede the use of sails. The maximum speed yet attained by steam-vessels is 20 m. an hour; the ordinary rate 8 to 15 miles.

The steam-engine employed to propel a vessel does not differ essentially from any other; but some modifications are necessary to suit the special circumstances under which they work. In ships of war, the cylinders are generally placed horizontally, and the whole machinery kept below the level of the water-line; in merchant vessels, vertical engines are more commonly used, with the cylinders inverted, placed right above the propeller-shaft. For working paddle-wheels, oscillating engines were, on the whole, the most common.

All the recent ships of the trans-Atlantic lines have been built of great size, and fitted with powerful engines. In length they are between 450 and 500 ft., breadth of beam 45 to 55 ft., and depth 30 to 40 ft. Their carrying capacity is between 5000 and 8000 tons. Many of them have been built with double bottoms, not only adding greatly to their strength and safety, but also giving space between the two which is divided into compartments for carrying water ballast. The engines of these ships are from 10,000 to 14,000 horse-power. The western passage has been made in a little less than six days. All these ships have 8 or 10 water-tight bulkheads, which makes sinking almost impossible. Steamers are also largely taking the place of sailing vessels in the carrying trade. Efforts are being made to attain greater speed than has been reached, and with steamers built entirely with the view to carrying passengers this will no doubt soon be accomplished. Twin or double screws have been used, but mainly on war ships; an appliance in the nature of a brake for suddenly stopping ships has been invented.

Since 1874 the problem of speed has been prominently before the minds of steam-ship builders, and next to the increase in the comfort of passengers secured by marine architects, their wonderful success in cutting down the time of ocean voyages deserves special consideration. The first condition for attaining a high degree of speed is the fineness of the ship's form, or of her "lines," for the reason that speed depends upon the least possible disturbance in the water surrounding the vessel; or, to put it more exactly, "the measure of efficiency of form for the maximum speed is inversely as the height of the waves of disturbance." When a ship is making the maximum speed for which it was designed, the waves of disturbance should not be very high, and the "wake" or area of disturbance left behind in the track of the vessel should be a narrow one. Mr. A. E. Seaton gives the following statement of the problem:

"It is usual to judge of the forms of ships by the relation they bear to rectangular blocks of the same dimensions: that is to say, a ship whose dimensions are—length, 100 feet; breadth, 20 feet; draft of water, 10 feet; and whose displacement is 12,000 cubic feet, would be said to have a fineness of 0.6, or that her fineness was 60 per cent., inasmuch as a rectangular block of the same dimensions would be 20,000 cubic feet. "This, however, is not an absolute test of the fineness of the water-lines of a vessel, and it can only be used as such on the assumption that the midship sections of ships are of similar form. The best test of the fineness of water-lines is made by taking the displacement as a percentage of a prism whose length is that of the ship and whose section is the same as the midship section of a ship; assuming, however, that the midship section of all ships is approximately that found in general practice to-day, in speaking of co-efficients it will mean the percentage of the rectangular block above named."

A great gain in speed, safety, and convenience was made when the screw was substituted for the old paddle-wheels. The paddle-engine is heavier and bulkier than the screw-engine; it is more expensive; it occupies the best part of the ship; it involves more wear and tear; and a paddle-steamer occupies more space; and there is always the

danger that if the shaft were to break, and one of the wheels were to fall clear of the ship, the vessel would be likely to capsize. The counterbalancing advantages of the paddle-steamer are these : it is more readily started and checked ; there is somewhat less rolling in heavy seas, and it requires less draft of water than the screw-steamer, though the employment of two screws, one on each side instead of one amidships, has reduced largely the necessary draft of the ship, which in the case of a single screw is to be not less than the ship's diameter. Moreover, there is superior safety in the twin-screw, both from the division of the engine-rooms and from the fact that if one engine breaks down it is unlikely that the other will do so at the same time ; while in the case of accident to the steering-gear, the ship could still be guided by the regulation of one or both of the engines. These advantages were partially demonstrated at the time of the accident to the Inman steamer, *City of Paris*, in 1890.

A very important aid to the construction of swift steamers was the introduction of the Siemens-Martin steel in 1875, which made it possible to work these ships economically. This steel is 50 per cent. stronger than iron, and thus admits of such a decrease in the weight of the hull as will allow the ship's lines to be made much finer while retaining the same carrying power. This material has reduced, too, not merely the weight of the hull, but that of the machinery, by nearly 60 per cent. Again, the introduction of the compound-engine, the triple-expansion engine, and latterly the quadruple-expansion engine have reduced the required coal-consumption from 4 pounds per indicated horse-power as low as $1\frac{1}{4}$ pounds of coal per horse-power.

Finally, the resistance of the hull of the ship by friction as it passes through the water, which is very great, has been largely reduced by smoothing the surface with a coating of enamel paint which is extremely slippery when in the water. This needs to be frequently renewed, as barnacles and vegetable growths adhere to it when affected by the sea-water, and ultimately reduce the speed by several knots.

The cost of the modern passenger steamships plying between New York and Europe is enormous, as is also the expense of each voyage. A first-class merchant steamer of the usual type costs about \$140 per ton weight of the hull and \$65 per indicated horse-power of the engines. A passenger steamer, of course, costs more proportionally, and in case it develops a high speed, it is rated at a very high figure. The Guion steamer *Alaska* of 7000 tons, cost \$1,750,000. The *Majestic* is valued at \$2,500,000. The gross cost of each passage made by the latter vessel is estimated in round numbers at \$20,000.

The most remarkable exhibitions of speed have been made by some of the modern vessels of war, among which are the fastest ships now in existence. Our own navy now contains some ships of very high speed. The *Baltimore*, *Philadelphia*, and *San Francisco* (protected cruisers) have a record over the measured mile of 19 knots per hour ; the *Newark*, on her trial trip in 1890, made 19.7 knots ; the new cruiser, known as "Cruiser No. 12," which has excited great interest among foreign naval experts, is to have a steaming capacity of 21 knots. The highest speed of any naval vessel is attained by the two United States torpedo-boats *Stiletto* and *Cushing*, the former making 22 and the latter 23 knots per hour. The swiftest cruisers in the English navy (the *Narcissus*, *Immortalité*, *Australia*, *Galatea*, *Orlando*, *Undaunted*, and *Aurora*) have a record of only 18.5 knots ; though in 1891 several of 20 knots were nearly completed.

It must be remembered, however, that the high speed of war-ships is generally intended to be maintained for a short time only. Therefore the achievements of vessels engaged in the transportation of passengers are more interesting, because they represent a degree of speed that is continued day after day with no intermission until the end of the voyage, and during the most unfavorable weather. It is in the Atlantic passenger traffic between England, France, Germany, and New York that the most remarkable voyages have been made, and the rivalry between the fast vessels of competing lines is so intense as to give to each voyage something of the character of an ocean race. From 1839 until 1862, the average length of a passage between New York and Queenstown had been from 10 to 12 days ; but in the last-named year, the Cunard paddle-steamer, *Scotia*, crossed in 8d. 4h. 30m., making the first great "ocean record," which it has since been the continual effort of ship-builders to cut down. In 1873, the Inman Line built the iron screw steamer, *City of Richmond*, which made a new record of 7d. 18h. 50m., soon reduced by its sister ship, the *City of Berlin*, to 7d. 14h. 12m. The White Star steamers, *Germania* and *Britannia*, cut this record down by several hours, as did the Guion vessel, *Arizona* ; but it was the Cunarder, *Servia*, that first made the voyage in less time than seven days (6d. 23h. 50m.). The six-day record has been broken by the White Star ships *Majestic* and *Teutonic*, by the Inman vessels, *City of New York* and *City of Paris*, and by the Cunard steamers *Campania* and *Lucania*, the last having made the best record up to Oct. 1, 1894, from New York to Queenstown in Sept., 1894, the voyage occupying 5d. 8h. 38m. On Aug. 5, 1891, the *Majestic* of the White Star line made a fine record, by completing the voyage from Queenstown to New York in 5d. 18h. 8m. The *Teutonic* (Aug. 19) made the same run in 5d. 16h. 31m. On the Pacific Ocean, the fastest passage was made in 1891 by the steamer *Empress of China*, from Yokohama to Vancouver in 10 days, two days less than any previous passage.

The following table gives the principal records of the voyages between New York and Queenstown, from 1836 to 1891 :

NAME OF SHIP.	Paddle or Screw.	When built.	Length on Water-line.	Breadth.	Draft.	Horse-power.	Tonnage.	Trial speed.	CYLINDERS.		Working pressure.	Time occupied on quickest passage.
									Diameter in inches.	Stroke in inches.

The best record between Southampton and New York was made by the American steamer *New York* in Sept., 1894, in 6d. 7h. and 14m.; and between Havre and New York by the French steamer *La Touraine* in 1891, in 6d. 21h. The approximate distance from Sandy Hook (N. Y.) to Roche's Point (Queentown) is 2800 miles; to Southampton, 3100 miles; and to Havre, 3170 miles.

Much thought has been given to the consideration of the question how far this increase in speed can be expected to continue. The greatest continuous speed of any ocean steamer so far has represented an average of not quite $23\frac{1}{2}$ knots per hour, developed by a horse-power of nearly 30,000, or of 15,000 upon each screw. It is now believed by experienced engineers that more than 30,000 horse-power cannot safely be applied to a single ship, and this limit has already been reached in the case of the Cunard steamship *Lucania*, a twin-screw steamer. This amount of power had never before been applied to both shafts of a twin-screw steamer, making a maximum of 30,000 horse-power, until the Cunarder *Campania* in 1893 made 560 knots (645½ statute miles) in one day.

The English engineer, Mr. J. R. Ruthven, in a paper read in 1890, expressed an opinion to the effect that "the screw has reached the limit of perfection," and added that the next great gain in ocean speed would result from the application of a new method of propulsion. Of those that have been suggested to take the place of the methods now in use, the turbine-wheels, pulsometers, ejectors, and pumps—all depending on the ejection of a jet of water into the sea—have hitherto proved unsuccessful by reason of the friction produced in the rapid passage through the pipes into the sea. This method received a very thorough test in 1866 by the British Admiralty, when the iron-clad *Waterwitch*, a vessel of 1200 tons, was fitted with a complete hydraulic propeller designed by Ruthven, but developed only 801 indicated horse-power and a speed of nine knots per hour. See an interesting paper by Mr. A. E. Seaton in *Scribner's Magazine* for July, 1891; and the articles, BULKHEAD; TWIN SCREW; IRON; SHIP; STEAM-ENGINE; PADDLE-WHEEL; SCREW PROPELLER; WHALEBACK.

STEAM PUMP. The simplest steam pump is the siphon pump, which acts upon the principle of the tromp (q.v.), except that the motion of steam causes the motion of the water, while in the tromp the motion of the water propels the air. A tube through which the steam is forced enters a hollow globe to a little beyond its center. On either side of this tube are openings into the globe for the entrance of water. These openings are much larger than the steam pipe. Opposite the latter is the exit tube for the mixed steam and water, having a trumpet shape and a length of about once and a half times the diameter of the globe. The rush of steam across the semi-diameter of the globe and through this funnel produces exhaustion in the lateral halves of the globe, into which spaces the water is forced by the external pressure of the air. The first direct acting piston pumps were probably invented by Mr. H. R. Worthington of New York, while making experiments for canal steam navigation in 1840. He patented a steam pump for feeding marine boilers in 1844. The steam cylinder was fed through a pipe which had a

valve at the other end within the boiler. To this valve there was adjusted a float which controlled the supply of steam, which extended the cylinder through a slide valve which was acted upon by a spring controlled by the motion of the piston. The present Worthington steam pump was evolved from this apparatus. It is a combination of pump and steam cylinder, driven by direct action and without intervention of fly-wheel or any appliance for producing rotary motion. The steam cylinder has the usual arrangement for the entrance and exit of steam, and the rod and piston is attached to a plunger of a double acting pump. At the middle of the piston rod, between the pump and steam cylinder, there is attached an arm which in passing to and fro strikes the long end of a lever, which changes the steam valves so as to alternately admit steam on one side or the other of the piston. Various improvements have been made to control the action of the slide valve. One method is the employment of a secondary cylinder and piston, to which steam is admitted by a sub-valve, acted upon by the main piston, near the end of the stroke. Another method is the employment of a fly-wheel. We will first mention those pumps having an attached crank and fly-wheel. Of these an example is furnished by the Eclipse steam pump, made at Pittsburg, Penn. The crank-shaft actuates a rocking lever, which moves the slide controlling the admission and exhaust of steam. The Clayton pump, made at Brooklyn, N. Y., has a yoke which couples the piston and pumping rods, and answers for the support of the crank-shaft journal. One end of the shaft, by suitable attachments, controls the valve, while the other supports the fly-wheel. These fly-wheel pumps have the advantage of a perfect control of the steam valve. The direct acting pumps have been the subject of many inventions, the principal object sought being the arrest of the piston at any rate of speed at a proper distance from the cylinder head. This has been accomplished by various devices. We have not space to describe the different forms of apparatus, but will mention the following as good examples:—Knowles's steam pump, which employs an auxiliary piston-valve or chest-piston, which has a reciprocating and rotary motion, which imparts motion to the main valve; Blake's steam pump, in which both the main and the auxiliary valves are plain, flat slide-valves, the auxiliary valve being a continuation of the ports of the main cylinder, and therefore forming a movable valve-seat; the Cameron steam pump, in which the steam-piston, at the end of the stroke, acts upon valves at either end of the cylinder, alternately admitting and exhausting steam; the isochromal steam pump, made at Hamilton, Ohio, which has a governor to regulate the strokes of the piston; and the National steam pump, in which the valve-gear consists of a main piston-valve, doing the work of an auxiliary piston, the valve stem performing the office of an auxiliary valve. See *illus.*, PULLEY, ETC., vol. XII.

STEAMSHIP. See STEAM NAVIGATION.

STEARIC ACID AND STEARINE. The composition of stearic acid is represented by the formula $C_{18}H_{36}O_2$; this acid being one of the solid fatty acids represented by the general formula $C_nH_{2n}O_2$. It exists as a glyceride (stearine) in most fats, and is especially abundant in the more solid kinds, such as mutton-suet. It is readily obtained by saponifying suet, and decomposing the hot solution of the soap by hydrochloric acid. The oily acids which are thus liberated are compressed between hot plates, by which means most of the oleic acid (q.v.) which is present is expelled. The solid residue is then to be repeatedly crystallized from alcohol, and afterwards from ether, till the fusing-point becomes constant at 158° F. (70° C.). If the final solution is allowed to cool slowly, the acid is deposited in beautiful, colorless, transparent rhombic plates. After fusion, it cools into a wax-like, glistening, crystalline mass, devoid of taste or smell. It is insoluble in water, on which it floats, but dissolves in alcohol and ether, its solution reddening litmus powerfully. When heated above its fusing-point it becomes decomposed. It may, however, be distilled under diminished pressure. Stearic acid forms both normal and acid salts. The only normal stearates which are soluble in water are the stearates of the alkalies, whose solutions are frothy and form a lather, but on the addition of an excess of water, separate into an acid salt which is deposited in silky crystalline plates, and the free alkali which remains in solution. The stearates of the alkalies are also soluble in alcohol. Chloride of sodium (common salt) has the property of separating the alkaline stearates from their solution. The stearates of the alkalies are the principal constituents of the different kinds of soap. The other stearates are insoluble. Stearate of lead, which is one of the constituents of lead-plaster, is readily formed by mixing solutions of stearate of soda and acetate of lead, when the stearate of lead falls as a heavy amorphous precipitate, sparingly soluble in alcohol or ether, but dissolving freely in oil of turpentine.

The *bassic acid* extracted from the oil of the seeds of *bassia latifolia*, a tree growing in the Himalayas, and the *stearophanic acid* obtained from the berries of *monospermum cocculus*, are identical with stearic acid.

The use of stearic acid in the manufacture of candles is described under the head CANDLE. See also OILS.

STEARNS, a co. in central Minnesota, having the Mississippi river for its e. boundary; drained by Sauk river and Sauk lake, with other small lakes and streams; 1334 sq. m.; pop. '90, 34,844, chiefly American. It is intersected by the Great Northern and the Northern Pacific railroads in the n.e. Its surface is hilly in the w., and well wooded with forests of maple, ash, oak, elm, etc. The soil is adapted to the production of grain, tobacco, wool, and dairy products. Live stock is extensively raised, and the

manufactures include carriages, wagons, agricultural implements, furniture, ale, beer, and flour. Co. seat, St. Cloud.

STEARNS, MARCELLUS LOVEWELL, b. Lovell, Me., 1839, was educated at Waterville acad. and Colby univ., and admitted to the bar. He served in the civil war, and lost an arm at the battle of Winchester; was a member of the constitutional convention of Fla., 1868, and speaker of the assembly for two terms. He was U. S. surveyor-gen. of Fla., lieutenant-gov., and gov. of that state, 1874-77.

STEARNS, WILLIAM AUGUSTUS, D.D., LL.D., 1805-76; b. Mass.; graduated at Harvard college, 1827; studied theology at Andover seminary; ordained pastor of a Congregational church, Cambridgeport, 1831; became president of Amherst college, 1854, retaining the office till his death. He published *Infant Church Membership; Life and Select Discourses of Samuel H. Stearns*; besides *Sermons and Addresses*, and articles in the *Bibliotheca Sacra*, *Biblical Repository* and *New Englander*. His son, long a merchant in Bombay, made a large gift in money for the chapel of Amherst college.

STEAROPTEN. See OILS.

STEATITE, or SOAP-STONE, a mineral principally composed of silica and magnesia, with more or less alumina and water. It is found massive, or sometimes assuming the forms of the crystals of other minerals which it has replaced. It is plentiful in many parts of the world, and is found in various parts of Britain. It is generally white, reddish white, or yellow. It is soft and greasy to the touch, easily cut, but broken with difficulty. It is used in the manufacture of porcelain. It writes readily on glass, and is used by glaziers for marking plates of glass before they are cut with the diamond. Tailors use it for marking cloth before they cut it. It is used by shoemakers, to give unctuousness to the heels of stockings, that new boots may more easily be tried on. It is sold for such purposes under the names of Briançon chalk, French chalk, and Venice talc. It readily absorbs oil or grease, and is used in powder for extracting spots of them from silken and woolen stuffs. It is the basis of rouge (q.v.). It is used for imitating engraved stones, being easily cut, and afterward hardened by heat; after which, it may be colored by metallic solutions. The *agalmatolite* or *figure-stone* of China is a kind of steatite, containing a little potash. Exquisite specimens of Chinese workmanship in this material are now familiar to every one. The earth eaten by the savages of the banks of the Orinoco and of New Caledonia is a kind of soft steatite.

STEDINGK, CURT BOGISLAUS LOUIS CHRISTOPHER, Count von, b. Pomerania, 1746; d. Stockholm; graduate of the university of Upsala, 1768; a soldier in the army; fought against Prussia; subsequently became lieutenant-col. of the royal Swedish regiment in the French army. He was an intimate friend of Count Fersen, and sailed with him in D'Estaing's fleet on the expedition to the West Indies, 1778, and as a volunteer in the American revolution. He distinguished himself as commander of a brigade at Granada and Savannah, 1779; was severely wounded at the latter. He was a member of the order of the Cincinnati; ambassador to St. Petersburg, 1790; delegate from Sweden to the peace conference at Paris, 1814.

STEDMAN, EDMUND CLARENCE, b. Conn., 1833; studied at Yale college; entered the profession of journalism in 1852 as editor of the *Norwich, Conn., Tribune*; and the following year edited the *Winsted, Conn., Herald*. In 1855 he went to New York, and soon began contributing poems to the *N. Y. Tribune*. At the outbreak of the civil war he was sent to the front by the *N. Y. World* as war-correspondent continuing until 1863. He contributed to the *Atlantic Monthly* and other leading magazines; in the meantime studied law, and in 1863 was private secretary to attorney-general Bates in Washington. In 1865 he entered into business in New York as a stock-broker, in which he continues. He has published *Alice of Monmouth and other Poems* (1864); *The Blameless Prince and other Poems* (1869); the prose works, *The Poets of America* (1886); and *Victorian Poets* (1875), etc. In 1891 he delivered a course of lectures at Johns Hopkins university, and in 1891-92, at Columbia college. He has edited with Ellen M. Hutchinson a *Library of American Literature* (1888-90). His *Victorian Anthology* appeared in 1895.

STEEDMAN, CHARLES, b. S.C., 1811; was midshipman in the navy, 1828; lieutenant, 1841; commander, 1855; captain, 1862; commodore, 1866; rear-admiral, 1871. He served in the bombardment of Vera Cruz; commanded brig *Dolphin* in Paraguay expedition, 1859-60; commanded the *Bienville* at Port Royal, 1861; silenced the batteries of St. John's Bluff, Fla., 1862; commanded sloop-of-war *Ticonderoga* in both attacks on Fort Fisher; commanding navy-yard, Boston, 1870-71; rear-admiral, 1871; retired, 1873.

STEEDMAN, JAMES BARRETT, b. Penn., 1818; in 1837 was engaged in the construction of the Wabash canal in Ohio; in 1849 organized an expedition to California but soon returned to Ohio. He was printer to congress, 1856-60. When the war broke out he was commissioned col. of volunteers, was present at Philippi, in Kentucky, at Perryville, Chickamauga, in Sherman's campaign of the Atlanta, and in the battle of Nashville. He resigned in 1866, then holding the rank of major-general. Under Johnson's administration he was collector of internal revenue at New Orleans. He d. 1893.

STEEL. See IRON: MINING.

STEELE, a co. in s.e. Minnesota, drained by Straight, Lester, and Cannon rivers; 430 sq.m.; pop. '90, 13,232, chiefly of American birth, with colored. The surface is undulating and diversified by lakes and small streams. Co. seat, Owatonna.

STEELE, a co. in eastern N. Dakota, formed in 1883; 720 sq.m.; pop. '90, 3777. Co. seat, Sherbrooke.

STEELE, FREDERICK, 1819-68, b. N. Y.; graduated at West Point in 1843; served in the war with Mexico; and was stationed in California from 1849-55. He was then ordered to the western frontier, and at the beginning of the civil war was in Missouri as maj. of the 11th infantry. In Sept., 1861, he was appointed col., and at the battles of Dug Spring and Wilson's Creek commanded a brigade. In 1862 he was promoted to brig.gen. of volunteers, and later assigned to the 13th army corps as maj.gen. of volunteers. He was in command in the Yazoo expedition and also at the capture of Arkansas Post. He was engaged in the Vicksburg campaign, and commanded the 15th corps at the capture of Little Rock. In 1864 he was in command of the department of Arkansas and aided Gen. Canby in the reduction of Mobile. In 1865 he was placed in command of the department of Columbia; in 1866 made col. of the 20th infantry, and was brevetted for his services during the war, maj.gen. of the U. S. army.

STEELE, Sir RICHARD, was born in Dublin in the year 1672. His father, who held the office of secretary to the duke of Ormond, was of an English family, but his mother was Irish; and the son appears to have inherited from her the impulsive ardor, tenderness, bright fancy, and reckless profusion immemorially ascribed to the Irish national character. He was educated at the Charter-house school, along with his illustrious friend Addison, and from thence was removed to Merton college, Oxford. Leaving college without taking a degree, he enlisted in the horse guards, for which imprudence he was disinherited by a rich relation of his mother, who had named him as heir to an estate in Wexford. In the army, he rose to the rank of capt., but was gay, thoughtless, and dissipated—always sinning and repenting, as he himself confesses. To impose a check on his irregularities, he wrote a religious treatise, *The Christian Hero*, published in 1710, the design of which was to show that no principles but those of religion are sufficient to make a great man. This public profession of seriousness had little effect on the volatile captain, and he next took to writing comedies. In 1701 he produced *The Funeral, or Grief à la Mode*; in 1703, *The Lying Lover*; and in 1705, *The Tender Husband*—the last a decided failure. About the same time, he obtained some fortune by marrying a West Indian lady, who survived the marriage only a few months; and in 1706, he got the appointment of gazetteer, with a salary of £300 per annum, and also the post of gentleman usher to prince George which added another £100 to his income. In the following year (Sept. 9, 1707), he married a Welsh lady, Mary Scurlock, who figures conspicuously in his correspondence as the "Dearest being on earth," "Dear Prue," and "Dear wife," to whom he addressed some 400 letters—admiring, apologetic, and passionate. A course of extravagance—town and country houses, horses and chariots—soon involved the pair in difficulties. Mrs. Steele had a fortune of £400 a year, and was thrifty; but the lady's mother had a life-interest in the estate, and was hard and uncongenial. Addison gave a loan of £1000, which was repaid within a twelvemonth; but he made other advances, secured by a bond on house and furniture. He put the bond in execution, sold the house and furniture, and remitted the surplus to his imprudent friend. For this seeming harshness Addison has been blamed; but it rests on good authority that the sufferer himself entertained no such feeling; he regarded the incident as a warning meant to do him service, and he met his friend again with his wonted composure and gaiety. In 1709, Steele commenced *The Tatler*, a periodical published thrice a week, containing short essays on life and manners, town gossip or *tattle*, and articles of foreign and domestic news, for which Steele's appointment of gazetteer furnished him with peculiar facilities. Addison joined cordially in this publication, and still more effectively in its successor, *The Spectator*, a daily literary journal of a higher tone and character, which was continued with unexampled success through 635 numbers. A third miscellany of the same kind, *The Guardian*, was extended to 175 numbers. Steele afterward attempted other periodicals, as *The Lover*, *The Reader*, etc., but these were short-lived. His fame rests on his essays in the *Tatler*, *Spectator*, and *Guardian*, to which he contributed respectively 188, 240, and 82 papers. In the keen political strife of that venal age, Steele fought courageously and honestly for the Hanover succession and whig principles. He lost his office of gazetteer, and was expelled the house of commons, for writing a pamphlet called *The Crisis*, in which he warned the nation that the Protestant cause was in danger. But when queen Anne died, and the whigs were again triumphant, Steele participated in the royal favor. He obtained an appointment in the king's household, was elected m.p. for Boroughbridge, and received the honor of knighthood. In 1717, Steele was nominated one of the commissioners for the forfeited estates in Scotland, and he seems to have made four annual visits to Edinburgh on the business of this commission. He was led into a controversy with Addison, a few weeks before the death of the latter, on the once famous peerage bill—a proposal by ministers for restraining the king from any new creation of peers, except upon the extinction of an old family. On this question Steele took the side of the crown, and fairly beat his opponent in argument and in temper, besides enjoying the triumph of seeing the bill thrown out. The friends, alas! met no more. The survivor struggled on among the controversies, embarrassments, and lawsuits; he was patentee of Drury Lane theater; and in 1722, he produced his admirable and successful comedy of *The Conscious Lovers*. His health now rapidly

failed. His wife had died in 1718, but he had children to solace his decline. The last three years of his life were spent in retirement in Wales, and there his checkered existence came to a close: he died at Llangunnor, near Carmarthen, on Sept. 21, 1729.

The essays of Steele eclipsed his dramas. His *Bickerstaff*, the *Spectator Club*, allegories, and short tales have the true, ever-living, dramatic spirit. In taste and delicate humor, he was greatly inferior to Addison; but in invention and insight into human character and motives, he was fully his equal. He knew the world better, and he sympathized with almost every phase of life and character except meanness and cruelty. He seems to have considered it to be his special mission to reform the minor vices and absurdities of English society. If his satire had been more keen and trenchant, or his moral lessons more formal and didactic, he could not have succeeded as he did; his essays were just adapted to the times—they insinuated morality and benevolence, and supplied innocent enjoyment mingled with instruction. The lively, natural writer and companion is never lost in the teacher, nor the gay captain of horse wholly absorbed in the author.

STEEL, Sir JOHN, R.S.A., an eminent Scottish sculptor, the son of a carver and gilder in Edinburgh, was b. at Aberdeen in 1804. He received his education as an artist at the Edinburgh academy, and afterward at Rome. On returning thence in 1830, he executed a colossal group of "Alexander and Bucephalus," which was instantly recognized as a work of great merit. The promise of this early work he has since amply fulfilled; and is now admitted to stand in the front rank of his profession. His chief works are in Edinburgh: the colossal figure of the queen crowning the front of the royal institution, which procured him the honorary appointment of sculptor to her majesty in Scotland; the statue of Scott in the Scott monument, a commission which was won in competition; the equestrian statue of the duke of Wellington (1852); statues of Wilson and Ramsay; the bronze statue of Burns in New York; and the equestrian statue of Prince Albert, at the inauguration of which in 1876 Steel was knighted. D. 1891.

STEEL TOYS. This is a manufacturing term much used in Birmingham, London, and elsewhere. It has a somewhat different meaning to that which would at first sight be given to it. Steel toys are small articles, such as cork-screws, buckles, boot-hooks, and a great variety of similar objects, when made of polished steel. Birmingham and Sheffield are the chief seats of this industry, which employs a large number of operatives and considerable capital.

STEELYARD. See **BALANCE**.

STEEN, JAN, a celebrated Dutch painter, was b. in 1636, or according to others in 1636, at Leyden, where his father was a brewer. He showed an early predilection for art, which led to his being apprenticed to a German painter, Nicholas Knupfer of Utrecht. Subsequently he became a pupil of Van Goyen, whose daughter Margaret he married. Very soon his repute became established. As he worked, however, in a slow and elaborate manner, his gains were insufficient, and he started a brewery at Delft. This enterprise promised fairly; but, according to tradition, he was by no means of steady business habits, and so bemused himself with his own beer that very soon he brewed no more of it. Little that is certain appears to be known regarding the subsequent life of Steen, but numerous unauthenticated anecdotes are in vogue, which, if it could be shown that they were true, would prove him to be a wretched drunkard; but a late biographer, Van Westerheene, throws considerable doubt on the accuracy of the popular impression. Steen died in 1679 or 1689, leaving his family in very destitute case.

As an artist of the Dutch school he ranks high; and his works are now much valued. In humor and spirit they are scarcely surpassed, and their coloring is clear, fresh, and delicate. At times he attempted historical subjects, but his success in these was not great. It was in homely and domestic scenes that his genius truly exhibited itself; and in this field he has scarcely since been quite equaled.

STEEPLE, the tower and spire, lantern, or other superstructure attached to a church. These are usually of stone, but in some cases are carried up from the floor in massive wooden framing.

STEEPLE-CHASE. This singular term is used to designate a kind of horse-race, run not on a prepared course, but across fields, hedges, ditches, and obstacles of every kind that may happen to be in the way. The name and practice are said to have both originated in a party of unsuccessful fox-hunters, on their return home, agreeing to try a race toward the steeple of a village church, the first who could touch the church with his whip to be the winner. This kind of sport soon became popular; and matches were made and sweepstakes entered into—the requirements of the course being simply two flagstaffs placed about 2 m. apart, from one of which the competitors started, made their way to the other, and returned to the starting-point. Each rider was allowed to go and come as he chose, but the country was often selected on account of its difficulty; high and strong fences, deep and broad ditches, and sometimes even swollen rivers having to be crossed and recrossed. Then came the more regular steeple-chase of modern times over a course marked out by flags, between which the rider must pass in order to win the race. This improvement was introduced about the end of last century, and no

further change took place till 1841, when *handicapping* began. This consists in the weighting of horses according to their supposed merits, without reference to age, size, or sex. The first handicap steeple-chase was run at Newport-Pagnell on April 20, 1841, and the sport has since become more and more popular in England, most of the spring and autumn meetings having their steeple-chases, for valuable stakes. Great crowds of people always attend, the very danger of the sport seeming to increase its attractiveness. Serious accidents are not unfrequent; and great courage, coolness, resolution, and judgment are requisite on the part of the rider in a steeple-chase.—The name is also applied to similar races for men.

STEERAGE, in a vessel, is the lowest class of accommodation for passengers.

STEERING APPARATUS, in antiquity, was always of one or usually two long oars, the rudder and helm having probably been invented by the Scandinavians, as all the words descriptive of their parts are old components of our language. A rudder with tiller is found on a seal as early as 1226, but no preventive tackle appear ever to be shown. The enormous length necessary for a tiller in a large ship causes the first improvement, the steering-wheel. This is a fixed windlass, on the barrel of which wind and unwind ropes carried over compound pulleys to the ends of the tiller, and to eyebolts in the side. The length of rope wound on the barrel will usually be somewhat over three times the angle traversed by the tiller, or between four and five turns to put the helm hard either way, from mid-ship. The next improvement was to suspend the rudder, not by pintles on the stern-post, but by a pivot at the bottom, leaving nearly a third on one side of the axis, as a counterpoise—the *balance-rudder*. This, very valuable on a screw ship, was needlessly powerful when under sail, and the counterpoise side was therefore made movable, and locked stiff when necessary—the *compound balance-rudder*. Still, the angle traversed being enlarged, the "work" of a steering-wheel was enormous, and in a sea a ponderous system of braces and preventer-tackle was necessary. About 1863 was introduced into the British navy the steam or hydraulic steering apparatus. The *Minotaur* had needed, to set her helm over 23°, 18 men at the wheels, 60 men at the relieving tackles, and 1½ minutes. To complete a circle required 7½ minutes. A balance-rudder would probably have increased the arc traversed to 40°. Fitted with the steam apparatus 2 men at the wheel set the rudder 35° in 16 seconds, making the circle in 5½ minutes. It is now usual to have a small auxiliary engine, an auxiliary wheel in case of accident, and for the old tiller is now substituted a yoke. There are many varieties of modern yoke wheels, both horizontal and vertical, working by pistons, by a ratchet, or by contrary-screws with levers. Steamboat rudders have long been worked from the house by the pilot, but the trouble of applying machinery to chains necessarily so long has always lain in the slack and the shock. The latest invention consists in attaching to each chain a piston which may receive steam on either side, one moving forward as the other moves aft, preventing all slack, and cushioning enough to deaden the shock almost entirely. An electrical steering apparatus has been invented, which is in use on the U. S. monitor *Miantonomah*.

STEEVENS, GEORGE, 1736-1800; b. England; educated at Eton, and King's college, Cambridge, became a draughtsman and an accomplished Shakespearean scholar, and published *Twenty of the Plays of Shakespeare, being the whole number printed in Quarto during his Lifetime*, in 4 vols. (1766). He was associated with Dr. Johnson in 1773 in the preparation of an annotated edition; and with Isaac Reed he published a revised edition (1785-93); the accepted standard for nearly 50 years. He assisted in the preparation of the *Biographia Dramatica*, and Nichol's *Biographical Anecdotes of Hogarth*; and contributed to Johnson's *Lives of the Poets*; Dodsley's *Annual Register*; and other works. His library, containing 1943 lots, was sold in 1800 for £2,740 15s.

STEFFENS, HENRIK, 1773-1845, b. Norway; studied at the university of Copenhagen; went to Germany, 1794, and through the writings and personal influence of Schelling zealously embraced the "philosophy of nature," was appointed professor of natural science at Halle, 1804; Breslau, 1811; and Berlin, 1831. In religion he was orthodox in his own country, a pietist at Halle; an Old Lutheran at Breslau, and a disciple of Schleiermacher at Berlin. In politics he advocated Jahn's Turner institutions and praised the commotions among the students of the Prussian universities. His autobiography, published in 10 vols., has been translated into English.

STEIN, CHARLOTTE ALBERTINE ERNESTINE VON, 1742-1827; b. Weimar; was a daughter of court marshal von Schardt; and in 1764 was married to baron Friedrich von Stein. Her intimacy with the poet Goethe commenced soon after his arrival at Weimar in 1775, and was broken off after his return from Italy in 1788. Her tragedy *Dido* is of literary interest, owing to its allusions to Goethe and to many of his contemporaries. She burned her letters to Goethe, but the poet's letters to her were edited by A. Schöll (1848) and Fielitz (1883). Letters addressed by Goethe and his mother to Frau von Stein's son were published in 1846. See *Charlotte von Stein*, by H. Düntzer (1874).

STEIN, HEINRICH FRIEDRICH KARL, Baron von, one of the greatest statesmen that ever conducted Prussian affairs, belonged to an old Rhenish-Franconian family, and was born at Nassau, Oct. 26, 1757. He studied at Göttingen from 1773 to 1777; entered

the service of Prussia in 1778, and in 1784 had risen to be at the head of the department of mines for Westphalia. In 1786 he visited England in company with his friends, the counts von Redern and Schlabbendorf, and carefully studied the institutions of that country, for which he conceived a high admiration, and sought to introduce them at a later period into Prussia. After several minor preferments, he was appointed, in 1797, president of the Westphalian chambers, where he displayed rare administrative talent. In Oct., 1804, he entered the Prussian ministry as chief of the department of indirect imposts, taxes, manufactures and commerce. In this capacity he effected important ameliorations, particularly by abolishing various restrictions on the internal trade of the nation; yet to his great grief and vexation he found himself incapable of modifying the policy that resulted in the French invasion and conquest. Of a thoroughly conservative and religious disposition, full of pious reverence for the past, so far as it possessed vital energy, but strongly opposed to the bureaucracy and military despotism; recognizing in the self-governing powers of communities and provinces the only practical guaranty of national liberty, yet, as a baron of the empire, hostile to the anarchic sovereignty of little states, he occupied a political stand-point which procured for him many adversaries and few friends. In 1807 he was dismissed from office by the king, and withdrew to his estate in Nassau; but the peace of Tilsit opened the eyes of his sovereign to the wisdom of Stein's policy, and in less than seven months he was recalled, with the approbation of Napoleon, who had as yet no idea of the deep and earnest patriotism of the minister. Stein's industry was untiring. Seeing clearly that, in a military point of view, Prussia was powerless for the moment, he set about developing her internal resources by attempting a series of administrative and political reforms, known as *Stein's System*—the principal of which were the abolition of serfage, with indemnification to the territorial lords; the subjection of the nobles to manorial imposts; equality of orders in the sight of the law; the universal obligation of military service; promotion in the state by merit alone, without distinction of caste; and the establishment of a municipal system analogous to that of England. Some of these reforms were carried out by Stein, and others by his successor, Hardenburg (q.v.). Meanwhile, he had become suspected by Napoleon. Among other things, an intercepted letter was brought to the French emperor, in which his policy was sharply criticised. Stein was obliged to resign (Nov. 1808), and retired to Austria, where he became the center of a secret national society—the *Tugendbund*. Napoleon, who bitterly hated patriots that stood in his way, confiscated his property. In 1812 Stein was summoned to Russia by the emperor Alexander, and contributed by his counsils to prepare the coalition against Napoleon. After the march of the allies into Saxony, he was appointed president of the council of all the German states; was a leader in all the military diplomacy of that stirring time up to the congresses of Vienna and Aix-la-Chapelle, in which, however, he took no part, owing to the intrigues of the Bavarian minister, acting for the lesser states of Germany, who knew well that he did not look with a favorable eye on their anarchic autonomy. The absolutists were also against him. Stein's active political career was now finished; henceforth he enjoyed some honorable functions, but no power, and died at Kappenberg, June 29, 1831.—See Pertz's *Leben des Freiherrn von Stein* (1855); Professor Seeley's *Life and Times of Stein* (1879); and the lives by Baur (1895) and Neubauer (1894).

STEIN'BOK. See BOUQUETIN.

STEINMETZ, KARL FRIEDRICH VON, b. Germany, 1796; entered the army in 1813 as a lieutenant; fought in the war against Napoleon, and was made a captain in the regiment of Kaiser Franz in 1835. After 1848 he was made governor of the academy of cadets at Berlin, and in the Austrian campaign of 1866 he won great distinction as commander-in-chief of the 5th army corps. He received the order of the Black Eagle, and the diet voted him a national donation for his services to Prussia. At the beginning of the Franco-German war of 1870 he was appointed commander-in-chief of the first army, but after the advance toward Metz, his army was united to that of Prince Friedrich Karl, who was placed in command. In Sept., 1870, Steinmetz was appointed governor-general of Posen and Silesia. He offered his resignation but the king declined to receive it. He was made a general field-marshal and placed in the suite. He d. 1877.

STEINITZ, WILHELM, b. Bohemia, 1837. He has been known as a chess-player for a number of years; he gained the first prize in the Vienna international chess tournament, 1873; tried with Winawer for the first prize in the Vienna tournament, 1882; and came second in the London tournament, 1883, won by Zukertort. He has traveled extensively, defeating the leading chess-players of the different countries, and giving exhibitions of his marvelous skill in simultaneous and blindfold play. He was chess editor of the *London Field*, 1873-83. He published a *Modern Chess Instructor* (1889); and edits the *International Chess Magazine*.

STEINTHAL, HEYMANN, b. Germany, 1823; after studying in Berlin lectured there on language and mythology; edited with Lazarus the *Zeitschrift für Völkerpsychologie und Sprachwissenschaft*, and has published *Die Classification der Sprachen* (1850); *Der Ursprung der Sprache* (1851); *Die Entwicklung der Schrift* (1852); *Das gegenseitige Verhältniss der Grammatik, Logik und Psychologie* (1855); *Geschichte der Sprachwissenschaft bei den Griechen* (1867); and *Abriß der Sprachwissenschaft* (1871 et seq.).

STELLARIA. See STITCHWORT.

STELLERINE, *Rytina*, a genus of *cetacea*, of the family *manatidae* (q.v.), of which only one species is known (*R. gigas*), about 25 ft. in length, a native of Behring's strait, and never observed since the middle of last century, so that it is supposed to be extinct.

STELLIO, a genus of the *agamidae* family of lizards. The *stellio cordylina* species is very common in Turkey and Arabia. A peculiar motion of its head has suggested the Mohammedan's tradition that the animal intends to mock the gestures made by them at prayer. For this supposed mockery they think it a duty to kill it.

STELVIO, PASS OF THE (Ger. *Stilfserjoch*), the highest carriage-road in Europe (9,055 ft. above the sea-level), leads from Bormio, on the Italian side of the Tyrolean Alps, near the head of the Valteline, to Glurns on the Austrian side. It forms part of the great road between Milan and Innsbruck, and was completed by the Austrian government in 1820-24, at an expense of 3,000,000 florins.

STEM, in botany, that part of the plant which, arising from the surface of the ground, and shooting upward as the root shoots downward, bears the leaves and flowers. Stems are either simple or branched. They are herbaceous or woody, solid or hollow, jointed or unjointed. Sometimes they are weak so as to be procumbent, although more generally firm and erect; sometimes weak stems are twining, or they are upheld in various other ways by the climbing habit of the plant. Stems are generally round, but sometimes compressed or angular. The arrangement of the leaves and branches, in reference to the stem, is symmetrical, but plants differ from each other in the nature of this arrangement. In the branching of trees, the symmetrical arrangement is often lost, as to the principal branches, in consequence of the death of some of them. In many plants the stem is obsolete, or so abbreviated as to be inconspicuous, forming a mere neck—the *crown of the root*—where the leaves and flower-stalks spring as at once from the root. Very important differences in the structure of stems distinguish the three great classes of plants—Acrogenous (q.v.), Endogenous (q.v.), and Exogenous (q.v.). Stems sometimes creep along the ground, or even under the ground.

STEM, of a ship, is that very powerful piece, or combination, of timber, which, being scarfed to the fore-end of the keel, rises nearly perpendicularly to form the bow and cut-water. To it are rabbeted the fore-ends of the planks. It is backed by an equally powerful timber called the stemson, bearing the same relation to it as the keelson (q.v.) does to the keel. See also SHIP-BUILDING.

STEMBEL, ROGER N., b. Md., 1810; entered the navy as a midshipman, 1832. At the beginning of the civil war he was made commander and took part in the actions of Belmont, fort Henry, Island No. 10, and several of less importance. He became capt. in 1866; was with the European squadron the next year, and in 1870 was made a commodore.

STENCILING, a method of printing letters or designs. The process consists in cutting out the pattern in a thin plate, usually of metal; this is then laid on the surface intended to receive it, and the color is rubbed into the cut space with a brush, the plate preventing the contact of the color, except on the space cut out. It is much used for wall and other surface-decoration, as it is a rapid and cheap process.

STENDAL, a t. of Prussia, province of Saxony, situated on the river Uchte, 36 m. n.n.e. of Magdeburg. Pop. '95 (with garrison), 20,666. It has a fine late Gothic cathedral, erected in 1423-50. It carries on important manufactures of woollens, cottons, tapestries, sugar, starch, etc. Stendal was formerly the capital of the *Altmark* of Brandenburg.

STENDHAL. See BEYLE, MARIE HENRI.

STENO, NICOLAUS, 1638-87; b. Copenhagen; d. Schwerin. He had long been famed for his anatomical discoveries, when in 1667 he devoted himself to geology, acquiring the right to be regarded as the father of palæontological science. He lived much in Italy and became a Rom. Catholic. In his latest years he wrote several religious and controversial works, and was made a bishop *in partibus* by the pope. See *Nature*, vol. xxv.

STENOGRAPHY. See SHORTHAND.

STEPHAN, HEINRICH VON, b. Pomerania, 1831; entered the Prussian postal service in 1848 and was rapidly promoted until in 1875 he became postmaster-general of the German empire. He introduced many reforms, and brought about postal treaties with foreign countries which have facilitated intercommunication and traffic. He has published *Geschichte der preussischen Post* (1859); and *Das heutige Aegypten* (1872). D. 1897.

STEPHANOCYPHUS MIRABILIS, a remarkable hydrozoön described by Prof. Allman, and for which he has founded a new order of *coelenterata*, the *comedusæ* (see *coelenterata* in article INVERTEBRATE ANIMALS). This organism is always associated with a species of sponge. It consists of a combination of chitinous tubes permeating the sponge, and opening on its surface by large orifices or oscula.

STEPHEN, the name of ten popes of the Roman Catholic church. It is only necessary to refer in detail to the following. **STEPHEN I.** was the successor of Lucius III.

in 254, and his pontificate (254–257) is memorable as affording a topic for the historians who discuss the question as to the early evidences of a Roman *primacy*. The history of Stephen I. is urged as an argument by each party in support of its own view. The advocates of the primacy infer, from several examples of the deposition of bishops by Stephen in various places, that a power equivalent to the modern primacy of Rome was even then acknowledged. The adversaries of the primacy contend that the resistance offered to Stephen by Cyprian (q.v.), on the rebaptizing of heretics, is altogether irreconcilable with the general recognition in the 3d c. of any supremacy on the part of the bishops of Rome.—STEPHEN III. plays a most important part in the history of the temporal sovereignty of the Roman see. He was a native of Rome, and was in possession of the see during the occupation (which practically dates from the year 752) of Ravenna, the exarchate, and the Pentapolis by Astolphus, king of the Lombards. That king having invaded Rome, and the Byzantine emperor, Constantine Copronymos, having left unheeded the appeals of Stephen, and the Romans for succor, Stephen had recourse to Pepin, king of the Franks. The latter in vain sent legates to Astolphus, and the pope returned to France with the legates to solicit in person the aid of the Frank monarch, whom he solemnly crowned. Pepin agreed to compel the Lombards to withdraw from these provinces (which form the portion of the states lately in occupation of the Roman see known as the “Legations”), and to bestow them on the see of Peter. The Lombard king made a promise to that effect; but on Pepin’s withdrawal, again renewed his pretensions, and marched upon Rome. Stephen, therefore, again recalled Pepin in a most curious letter written in the name and person of St. Peter, an invitation with which Pepin at once complied; and having again forced Astolphus to withdraw, he again (notwithstanding a demand from the Byzantine emperor for their restoration to the empire) reinstated the Roman see in its sovereign rights. Stephen died in 757.—STEPHEN VI., elected in 896, has supplied to historians much matter of discussion, from his strange proceedings in disinterring the corpse of his penultimate predecessor, Formosus, stripping it of its pontifical garments, and condemning it, after a juridical procedure, to lay burial. The circumstances of this curious conflict are not fully understood.—STEPHEN X. was one of the remarkable series of reforming popes in the 11th c., who are believed to have been elected under the influence of the celebrated Hildebrand, and who by their energetic rule, prepared the way for that great scheme of ecclesiastical organization of which the pontificate of that eminent man, under the name of Gregory VII. (q.v.), was the final development. It ought to be observed that, although in the series of the popes (q.v.) printed in this *Encyclopædia* ten pontiffs named Stephen are recited, other catalogues reckon but nine; the discrepancy arising from the omission by some of Stephen II., who was elected in 752. This pontiff died before consecration, and is therefore by some excluded from the series of popes; but, as his election was complete and canonical, we have included his name in our general catalogue.

STEPHEN, SAINT, THE DEACON, called also the proto-martyr, or earliest of the Christian martyrs, was one of the seven deacons whose appointment is related in the 6th chapter of the Acts of the Apostles. The circumstances of his martyrdom are related in the same chapter. His festival is fixed during the festivals which accompany that of Christmas. It is kept with great solemnity, both in the east and in the west. His relics were believed to have been discovered in the beginning of the 5th c., the “discovery” being commemorated by a festival held on the 3d of August.—In the calendar of the Roman Catholic church are several other saints of the same name, of whom perhaps the most remarkable is Stephen, king of Hungary, in the early part of the 11th century. He died in 1038. His memory is held in great veneration throughout Southern Germany, and churches are met everywhere, dedicated to his name.

STEPHEN, King of England, was the third son of Stephen, count of Blois, by Adèle or Alise, daughter of William the Conqueror, and was consequently nephew of Henry I., and cousin of Matilda, daughter of Henry. He was born in 1105, brought over to England at an early age, and became a favorite with his uncle, who bestowed on him large estates, both in that country and in Normandy, and procured for him a marriage with Mahout, or Matilda, daughter of Eustace, third count of Boulogne, and younger brother of the famous Godfrey of Bouillon. By this marriage Stephen not only inherited the earldom of Boulogne on the death of his father-in-law (1125), but also became related to the royal family of Scotland, for his wife’s mother, Maria, was a daughter of Malcolm Canmore. When his uncle Henry resolved to settle the crown on his daughter Matilda, whose first husband was Henry V., emperor of Germany (whence she is often spoken of as the “Empress Maud”), he naturally relied on his project receiving the support of his nephew; and at a council held in London, Jan., 1127, Stephen, along with all the other dignitaries of the land, lay and ecclesiastical, took the oath of fealty to Maud. A few months later, the widowed empress married Geoffrey Plantagenet (q.v.). On the death of Henry I. (Dec. 1, 1135), Stephen, knowing well the temper and wish of the English people, hurried over to England from Normandy, where he had been in attendance on his dying uncle, and before the year was out had got himself surrounded by a powerful body of the nobles and clergy and crowned at Westminster. His usurpation of the throne was confirmed by a bull of pope Innocent. But Stephen was doomed to find his crown a crown of thorns. Although a gallant, generous, handsome prince, immeasurably su-

perior in personal and royal virtues to Maud (who was suspected of having murdered her first husband, who quarrelled with her second, and was altogether a fiery, insolent, unwise, and exasperating female): yet it must not be forgotten that on Stephen rests the responsibility of causing a civil war as sanguinary, if not as protracted, as the famous *Wars of the Roses*. Listen to the *Saxon Chronicle*: "In this king's time, all was dissension and evil and rapine. . . . Thou mightest go a whole day's journey, and not find a man sitting in a town, nor an acre of land tilled. The poor died of hunger, and those who had been men well-to-do begged for bread. Never was more mischief done by heathen invaders. . . . To till the ground was to plough the sands of the sea. This lasted the nineteen years that Stephen was king, and it grew continually worse."

We have not space to narrate in detail the struggle of these nineteen years. It is enough to say, that in Feb. 1141, after five years of the hardest fighting imaginable—against David of Scotland, uncle of Maud, who had taken up arms for his niece (see STANDARD, BATTLE OF THE); against Robert, earl of Gloucester, natural son of the late king Henry, who had also raised the standard of his half-sister, against individual nobles who simply wished to live in anarchy and barbarous independence, and finally, against the power of the church, which he vainly sought to diminish—he was taken prisoner by the earl of Gloucester, and placed in chains in the castle of Bristol. Maud was now elected queen by her own party, but her rapacity and other bad qualities soon made her rule intolerable, and the wife of the imprisoned Stephen (also called Maud or Matilda) found it possible to continue the war, by the help of the Londoners, who were staunch adherents of her husband. Stephen obtained his liberty in exchange for the earl of Gloucester, who had fallen into the hands of Stephen's friends at Winchester, and the war was resumed with greater violence than ever. The death of the earl of Gloucester, in 1146, forced Maud to take refuge in Normandy; but a conspiracy of nobles, headed by Ranulph, earl of Chester, and another quarrel with the church kept Stephen's hands as full of work as before, and no sooner were these matters settled, than Maud's son, young prince Henry, appeared in England (1153), at the head of an army to support his claim to the throne. Fortunately for the nation, so sadly wasted and desolated, a compromise was effected between the two rivals, which saved the necessity of further bloodshed—Stephen agreeing to acknowledge Henry as his successor. Stephen died at Dover the year after (Oct. 25, 1154).

STEPHEN, Sir JAMES FITZ-JAMES, b. London, 1829; eldest son of James and bro. of Leslie. He graduated at Cambridge, 1852; and was called to the bar at the Inner Temple, 1854. He was recorder of Newark-on-Trent, 1859-69, and legal member of the council of the gov.-gen. of India, 1869-72, doing much, during his three years in India, to consolidate, abbreviate, and simplify Indian law. He was appointed prof. of common law to the Inns of Court, 1875; in 1877 was nominated knight commander of the Star of India, and judge of the high court of justice, 1879. He published *A General View of the Criminal Law of England* (1863); *Liberty, Equality and Fraternity* (1873); *Digest of the Law of Evidence*, and *Digest of the Criminal Law* (1877); and *A History of the Criminal Law of England* (3 vols., 1883). He died in 1894.

STEPHEN, LESLIE, b. Kensington, Eng., 1832; son of Sir James. He graduated at Trinity Hall, Cambridge, 1852, and was for some years fellow and tutor of his college, removing, 1864, to London, and engaging in literary pursuits. He was a frequent contributor to the *Saturday Review* and other periodicals; edited the *Cornhill Magazine*, 1871-82; and has published the following works: *Hours in a Library*, 3 vols., 1874-76-79; *Essays on Free-thinking and Plain-speaking*, 1873; *History of English Thought in the Eighteenth Century*, 1876; *The Science of Ethics*, 1882; and *Johnson, Pope, and Swift*, in the *English Men of Letters* series. He is also the editor of *The Dictionary of National Biography*, the first volume of which appeared 1885, and the fifty-second in 1897. Stephen is known as one of the leaders of the modern school of agnostics, but he is remarkable less for originality than for the clear vigorous manner in which he presents the accepted doctrines of his school. As a literary critic he is able and impartial.

STEPHENS, a co. in n. Texas, drained by the Clear Fork of Brazos river; 900 sq. m.; pop. '90, 4926. Co. seat, Breckenridge.

STEPHENS (Fr. *Estienne*). The family of the celebrated printers and publishers of this name (descended from a noble Provençal family) is found settled at Paris toward 1500 in the person of Henry Stephens, supposed to have been born about 1460, and died in 1520. In Paris Henry carried on the business of printer and book-seller for upward of 20 years. In 1526 Robert, his second son, b. 1503, is found in possession of the business. Every year of Robert's life is marked by the issue from his printing-press of several volumes, many of them masterpieces of art, and all of them surpassing anything of the kind previously seen in France. He was at once printer, publisher, commentator, and author. Though prosperous, he showed unmistakably that truth—or that which to him was truth—was of more value in his eyes than worldly gain. Having secretly become a convert to the doctrines of the reformation, he endeavored for some time to reconcile his convictions with the outward demeanor required by his position. But the convictions were too strong, or the nature of the man too truth-loving. His Bible of 1545, and his Greek Testament of 1549, each drew down upon him a public prosecution; and though the prosecutions failed legally, they were disastrous to his private fortune. Having first sent his family to Geneva, he followed them there in 1551. Robert, his second son,

shortly afterward returned to Paris, where he resumed his father's business, returning to the Roman Catholic church.

In flying from Paris to Geneva, the Stephens family found that they had but exchanged Roman Catholic for Protestant persecution.

Henry the second, born at Paris in 1528, and succeeding his father Robert on his death in 1559, was repeatedly called before the council, reprimanded, ordered to print cancels, and excommunicated. Though Henry possessed the same literary industry and ability as his father, he was unfortunately deficient in his father's practical turn of mind. Devoted to his art and to his calling, he seems to have been utterly wanting in worldly prudence. In two years we find that he had revised and published more than 4,000 pages of Greek text; while at the same time he was writing his *Apologia pro Herodoto*, a work of formidable length and learning. Rendered nervous and irritable by an overworked brain, and by pecuniary difficulties, which were gathering fast around him, the petty surveillance and censorship of the pious pastors of Geneva became intolerable to him. Traveling, originally undertaken from literary curiosity, grew into a necessity of life. In 1578 he visited Paris, where for several years he became a hanger-on of the court of Henry III., who bestowed upon him a pension, which the state of the royal exchequer rendered merely a nominal one. Quitting Paris, he wandered in poverty over Europe, his own family often ignorant of where he was to be found. He died at Lyons in 1598. Great as a publisher and commentator, Henry Stephens does not seem to have possessed much power as an original thinker. His mastery of Greek seems to have been almost complete, and as a critic of the French language he is still esteemed in France. See *Caractères et Portraits Littéraires du Siècle XVI.*, by M. Leon Feugere (Paris, 1864); also article in *Quarterly Review* (Lond. April, 1865); and article "Estienne," in the *Nouvelle Biographie Générale*; Bernard, *Les Estiennes*; Renouard, *L'Imprimerie des Estiennes*.

STEPHENS, ALEXANDER HAMILTON, LL.D., b. Ga., 1812; graduated at Franklin college, Athens, Ga., in 1832, at the head of his class. He studied law, and was admitted to practice at the bar in 1833, in Crawfordsville, in his native county. In 1836 he was elected a member of the lower house of the Georgia legislature, in which he served five years. In 1842 he was elected to the state senate; and the following year to congress, as a whig, retaining his seat until 1859, when he resigned. After the Kansas struggle in congress he became a democrat, and supported the Lecompton constitution in 1858. On the outbreak of secession in the south, Mr. Stephens opposed it, defending the union in a number of public speeches. He, however, changed his attitude when it was evident that opposition was unavailing; was elected to the vice-presidency of the new confederacy, and delivered addresses at Atlanta and Savannah, Ga., in which he earnestly attacked the north, and sustained the new government in the south. He was one of those among the confederate leaders who boldly asserted the right of slavery *per se*; and who conceded that the southern design was to found a government upon the specific declaration of that principle. Mr. Stephens was a consistent follower of the doctrines of Mr. Calhoun; and his early opposition to secession was doubtless based upon his disbelief in its possibility of success, and his judgment against the policy of the movement. He continued to hold his office during the civil war. In May, 1865, after the surrender of Gen. Lee, he was arrested and imprisoned in Fort Warren, Boston harbor, but was released in Oct. After the war Mr. Stephens repeatedly represented his state in congress, where, though in infirm health, his advice was frequently sought on important measures. He published *A Constitutional View of the Late War Between the States*, and a *Compendium of the History of the U. S.*; inaugurated gov. Georgia, 1882; d. March 4, 1883.

STEPHENS, ANN SOPHIA (WINTERBOTHAM), b. Derby, Conn., 1813; married Edward Stephens, a printer of Plymouth, Mass., and removed to Portland, Me. She established *The Portland Magazine*, 1835; editor of *The Portland Sketch Book*, 1836. In 1837 she removed to New York, contributed to the magazines, and wrote a prize story, *Mary Derwent*, receiving \$400. This brought her into notice, and she at once became a popular magazine writer. She also wrote many novels: *Fashion and Flame* (1854), translated into French; *The Old Homestead*; *The Heiress of Greenhurst*; *Married in Haste*, etc., and edited several magazines and newspapers. D. 1886.

STEPHENS, JOHN LLOYD, 1805-52; b. N. J., graduated at Columbia college, 1822. He studied law in the Litchfield school, and was admitted to the New York bar, where he practiced 8 years. In politics he was an influential democrat. In 1834 he visited Europe and Egypt, and on his return published an account of his travels in the eastern and northern countries. In 1839 he was sent to Central America as special ambassador, and in 1842 again visited Yucatan. His *Incidents of Travel* in these countries form the best of all his popular and valuable works, and contain much original information in regard to American antiquities. He was a director of the "Ocean Steam Navigation company," originating the first American line of transatlantic steamships, and was president of the Panama railroad.

STEPHENS, WILLIAM, 1671-1753; b. England; graduated at King's college, Cambridge; studied law at Middle temple; was a member of parliament, 1696-1722; removed to Charleston, S. C., 1730; at the recommendation of Oglethorpe was appointed secretary of the trustees in Georgia; president of the colony, 1743-50. His *Journal of the*

Proceedings in Georgia was printed in 3 volumes. His son wrote his biography, entitled *The Castle Builders*.

STEPHENSON, a co. in n. Illinois, adjoining Wisconsin, drained by the Pecatonica and the Yellow rivers; traversed by the Chicago and Northwestern, the Chicago, Milwaukee, and St. Paul, and the Illinois Central railroads; about 560 sq. m.; pop. '90, 31,338, chiefly of American birth. The surface is rolling. The soil is fertile. The principal productions are corn, wheat, oats, rye, butter, and wool. Co. seat, Freeport.

STEPHENSON, GEORGE, was born on June 9, 1781, in circumstances of great poverty, his father having to maintain a family of six children on 12s. per week, earned by tending a colliery engine at Wylam, near Newcastle. George's first employment was herding cows at 2d. per day, from which he was promoted to hoeing turnips at 4d.; subsequently, he was appointed fireman at Midmill colliery, and at 15 we find him rejoicing on his salary being raised to 12s. a week. As fireman, he applied himself to diligent study of the steam-engine, taking his machine to pieces during his leisure hours, and thus gaining a thorough practical knowledge of it. At Black Callerton colliery, in 1801, by dint of mending shoes and cleaning watches, in addition to his regular employment, Stephenson contrived to save his first guinea. At 21 he had saved as much as enabled him to furnish a cottage in a humble way, and on Nov. 28, 1802, he was married to a young woman named Fanny Henderson. She died in 1804, while her husband was brakesman at Killingworth colliery. The early life of Stephenson presents a record, whose interest cannot be surpassed, of a contest between determined purpose, industry, and sagacity on the one hand, against poverty on the other. Slowly, inch by inch, we find the inward forces gaining ground upon the outward. Out of his humble gains he contrived to pay 4d. a week for lessons in reading, writing, and arithmetic, which were conned over at night, and mastered by the light of his engine-fire. On one occasion, indeed, so hard had the tide gone against him, that even he had nearly given way to despair. "I wept bitterly," he says, in allusion to an intention he had formed of emigrating—"for I knew not where my lot in life might be cast." In 1815 the invention of a colliery safety-lamp, the "Geordie," brought his name before the public. The fact of his invention being almost simultaneous with that of sir H. Davy, gave rise to a long controversy between their respective friends and supporters. In 1819 Stephenson married his second wife, Elizabeth Hindmarsh, the daughter of a farmer at Black Callerton. It was at Killingworth colliery that he constructed his first locomotive. At first, it was not very efficient; but, subsequently, the grand improvement of the "steam-blast" carried his experiment to a triumphant issue. Further improvements followed, and in 1821 Stephenson was appointed engineer for the construction of the Stockton and Darlington railway; the line on its completion, being partially worked by means of his great invention. The rapid growth of the trade of South Lancashire, together with the unpopular management of the Bridgewater canal, gave rise, in 1821, to the project of a railway between Liverpool and Manchester. Stephenson was chosen engineer. That he proposed to work the line with an engine which was to go at the rate of 12 m. an hour, was a fact held up as of itself sufficient to stamp the project as a bubble. "Twelve miles an hour!" exclaimed the *Quarterly Review*—"as well trust one's self to be fired off on a Congreve rocket."

When the bill ultimately passed, on Mar. 16, 1825, Stephenson was appointed principal engineer, with a salary of £1000 a year. After inconceivable difficulties, the line was completed in 1829. There then ensued the memorable competition of engines, resulting in the complete triumph of Mr. Stephenson's "Rocket," which, to the astonishment of every one except himself, was found capable of traveling at the till then undreamt-of rate of 35 m. an hour. "Now," exclaimed one of the directors, "George Stephenson has at last delivered himself." While occupied in carrying out the vast system of railway which soon overspread the country, Stephenson's home was at Alton Grange, near Leicester. He saw but little of it, however, as he was often traveling on business for weeks at a time. During the three years ending 1837, he was principal engineer on the North Midland, York and North Midland, Manchester and Leeds, Birmingham and Derby, and Sheffield and Rotherham railways. In 1836 alone, 214 m. of railway were put under his direction, involving a capital of five millions. In the autumn of 1845 he visited Belgium and Spain for professional purposes. On his way home he was seized with pleurisy, from which attack he does not seem ever to have thoroughly recovered. He occupied his declining years with the quiet pursuits of a country gentleman, indulging his love of nature, which, through all his busy life, had never left him. He died at his country-seat of Taptop, Aug. 12, 1848. The leading feature of his mind was honesty of purpose, and determination in carrying it out. "I have fought for the locomotive single-handed for nearly 20 years," he says; "I put up with every rebuff, determined not to be put down." Toward trickery and affectation he never concealed his contempt, while honest merit never appealed to his liberality in vain.—See *Lives of Engineers*, by Samuel Smiles, vol. iii. (Lond. 1862).

STEPHENSON, ROBERT, only son of George Stephenson, was b. on Oct. 16, 1803. When a boy he attended a school in Newcastle. In 1820 his father's improving circumstances enabled him to send Robert to the university of Edinburgh, where he seems to have made excellent use of his time. In 1823 we find him assisting his father in the survey for the Stockton and Darlington railway. Subsequently, he took an active part

in the locomotive engine-works started by his father at Newcastle. In June, 1824, he went to Mariquita, in South America, on an engineering appointment; but this not suiting him, at the end of three years he returned home by the United States and Canada. He then assumed the management of the Newcastle business. During the discussion as to the power to be employed on the Liverpool and Manchester line, he was in constant communication with his father, to whom his quick perception and rapid judgment were of great assistance. Shortly after the completion of this line, he was appointed engineer of the Leicester and Swannington railway. Subsequently he was appointed joint managing engineer, along with his father, of the London and Birmingham line, the execution of which immense work was ultimately almost wholly intrusted to him. In 1829 he married Frances, daughter of John Sanderson, merchant in London. She died in 1842 without issue; and he did not marry again. The London and Birmingham line was completed in such a manner as to raise Stephenson to the very highest rank in his profession. Business now flowed in upon him. In one parliamentary session we find him engaged in 33 new schemes. Projectors thought themselves fortunate if they could procure his services on any terms. The work which he got through was enormous, and his gains large beyond what had then been known in his profession.

The Britannia tubular bridge, of which undertaking Robert Stephenson was the master spirit, is one of the most remarkable monuments of the enterprise and engineering skill of the present century. It was completed on Mar. 5, 1850, at a cost of £234,450. Stephenson lived to repeat his splendid achievement in the bridge across the St. Lawrence at Montreal, and in the two bridges across the Nile at Damietta. In 1847 he was returned to the house of commons as member for Whitby. On Aug. 15, 1849, he completed the high-level bridge at Newcastle, and in the following year the great viaduct across the Tweed at Berwick. In 1855 the emperor of the French decorated him with the legion of honor. At home the university of Oxford made him D.C.L. In the same year he was elected president of the institute of civil engineers. The immense amount of work which he went through both at home and abroad proved too much for his constitution, originally delicate; while in Norway, in 1859, he was seized by the illness which soon afterward ended his illustrious career. He died on Oct. 12, 1859. He was buried in Westminster abbey. It was as a workman that Robert Stephenson was great, his political views being at times rather narrow. Contrasting him with his great rival, Brunel, it has been said that the ambition of the latter was to make a great work; that of the former to make a work which would *pay*. Robert Stephenson inherited the kindly spirit and benevolent disposition of his father.

STEPNIAK, the pseudonym of MICHAEL DRAGOMANOF, born Gadiatch in Little Russia, 1841; studied at the gymnasium of Poltava and at the univ. of Kiev; in 1864 was appointed prof. of ancient history in the latter place, but his radical ideas led to his expulsion in 1876. He then went to Geneva and undertook the publication of the Ukraine review *Gromada*, in which he advocated the adoption of a federal government for Russia. At the same time he contributed articles on Russian subjects to various European periodicals, and issued a number of historical pamphlets. In 1882 his *Underground Russia* appeared in Italy and in the Italian language under his now famous pseudonym, followed in 1885 by *Russia under the Czars*. These books give a vivid insight into the political condition of the Russian empire, and especially of the machinations of the Nihilists. Their wide popularity led to many attempts to penetrate the secret of their authorship, but it was not till 1885 that the identity of Stepnjak was established. In 1891 he visited the United States. D. 1896.

STEPPEs, the distinctive name applied to those extensive plains which, with the occasional interpolation of low ranges of hills, stretch from the Dnieper across the s.e. of European Russia, round the shores of the Caspian and Aral seas, between the Altai and Ural chains, and occupy the low lands of Siberia. The word, which is of Russian origin, denotes primarily an uncultivated plain of great extent, and has been applied by geographers to the above-mentioned regions as expressive of their flat, semi-barren, treeless character. In spring and early summer the steppes are clad with a thin covering of green herbage, become parched and barren under the scorching heat and drought of June, and in winter are hid beneath a thick covering of snow, which, raised in huge white thin clouds, and driven hither and thither by furious storms, brings destruction to every living creature within its sweep. The monotony of the steppe is as fatiguing to the traveler as is that of the sandy, arid desert. For hundreds of leagues his eye is compelled to endure the same unvarying level of scanty herbage, unbroken by tree or bush, and bounded by the utmost limits of the horizon; only in spring, while the vegetation is succulent and fitted for pasture, is the solitude broken here and there by herds of horses and cattle and their mounted guardians. In autumn, when the tall herbage, withered by the heats of summer, has been rooted up and broken by violent winds, it becomes gathered and rolled together into enormous balls, sometimes of from 9 to 11 yards in diameter. Here and there are tracts which offer some inducement to the agriculturist; such are the steppe e. of the Dnieper, that between the Don and Volga—of inferior fertility, but rich in coal—and the steppes of south-western Siberia, especially those in the government of Tomsk, all of which have been partially colonized; but a very wide extent is hopelessly barren.

STERCULIA CEE, a natural order of exogenous plants, closely allied to *malvaceæ* and *hytneriaceæ*, and consisting of large trees and shrubs, natives of warm climates. About 130 species are known. The flowers of some are irregular, and in some they are hermaphrodite, in others unisexual. Many species, particularly of the sub-order *bombaceæ*, are trees of gigantic size, among which is the baobab or *adansonia* (q.v.) *digitata*. The bark of some species is very fibrous, so that it is made into ropes and coarse cloth. The light wood of *ochromalagopus* is used in the West Indies instead of cork.

STERE (Gr. *stereos*, solid), the name given to the unit of cubic measure in the French metrical system. It is a cubic meter (q.v.), and equivalent to 35.3165818168 English cubic ft., or 1.3080215487 English cubic yards. The *decastère* is equal to 10 steres, and the *decistère* to the tenth part of a stere. This measure is much used for wood, especially firewood.

STERELMINTHA (Gr. *stereos*, solid, and *helmins*, an intestinal worm), a term suggested by Prof. Owen, and generally adopted to signify those intestinal worms which have no true abdominal cavity, and which were called "parenchymatous" by Cuvier. See **CELELMINTHA**.

STEREOCHROMY, a process of wall-painting, invented by Prof. J. N. von Fuchs, of Munich, professed to be superior to fresco-painting, inasmuch as it will admit of any part of the picture being retouched, as in the case of oil-paintings. It is also more durable, being protected by a varnish from the effects of the atmosphere.

STEREOSCOPE (Gr. *stereos*, solid, and *skopein*, to see), an optical instrument of modern invention, by means of which pictures of objects possessing three dimensions are seen not as plane representations, but with an appearance of solidity or relief, as in ordinary vision of the objects themselves. The more recondite principles of the stereoscope, which are of high interest and importance in their bearing on the philosophy of perception, will be fully considered under **VISION**, **BINOCULAR**. The present article will be limited to an historical sketch of its invention and subsequent developments, coupled with an exposition of the optical and mechanical details of its construction.

The essential principle of the stereoscope, the first conception of which by prof. Wheatstone justly ranks as one of the most brilliant optical discoveries of the age, may be thus explained. It is an obvious fact that the eyes being separated by a certain interval of space, all solid objects so near to the observer as to be seen with a sensible convergence of the optic axis, necessarily form retinal pictures, differing as to their perspective projections for each eye. Singular to say, the true import of this plain fact was wholly unsuspected prior to the investigations of Prof. Wheatstone, who, in his first paper on this subject, published in the *Philosophical Transactions* for 1838, clearly established the important conclusion that this dissimilarity of the retinal images is made to subserve an important end in the use of our visual organs—that it is, in fact, the principal originating cause of our immediate perception of the solidity (or relief) of objects adjacent to the sight. The problem he set himself to investigate was: "What would be the visual effect of simultaneously presenting to each eye, instead of the object itself, its projection on a plane surface as it appears to that eye?" and in order to bring this question to the test of experiment, he devised an instrument which he named the stereoscope.

The pictures being attached to the slides, the observer places himself with his nose close to and immediately in front of the vertical angle made by the reflectors, so that the view by each eye is limited to the rays reflected by its appropriate mirror; the pictures are then seen, as it were, behind the mirrors, and, the eyes being made slightly to converge, either by an effort of the will or by drawing the slides a little forward, the effect of either of which is to refer the reflected images to the same part of space, the observer sees no longer mere pictorial resemblances, but, to all appearance, the objects themselves, exquisitely modeled, occupying a certain extent of space, and standing forth with a substantiality of aspect truly wonderful. At the outset the only stereoscopic pictures obtainable were the outlines of geometrical solid figures, which it was possible for a skillful artist to depict with perspective projections adapted for the right and left eye respectively; and the pictures so prepared excited the greatest interest and admiration. They, moreover, abundantly exemplified the truth and importance of the binocular principle, though the universality of its application to purposes of pictorial illustration only became apparent on the introduction and gradual improvement of the photographic arts. In 1849 sir David Brewster originated that convenient, portable, and in all respects admirable form of the stereoscope which is now in general use over the whole civilized world. For this—the lenticular stereoscope—the pictures (taken, be it remembered, from two different points of view), are mounted side by side, on a piece of cardboard, and, being placed in the instrument, are viewed through semi-lenses, fixed at a distance apart of the two eyes. To effect the displacement of the pictures, so that they shall be referred to the same part of space, which we have above defined to be an essential condition, sir David Brewster most ingeniously availed himself of an optical principle, which enabled him at the same time to fulfill several collateral ends of considerable importance. This principle may be described as follows: If an object be viewed through the center, or, more properly, along the axis, of a convex lens, it will be seen exactly in front of the eye; i.e., in a line with the eye, the center of the lens, and the actual place of the object. If now the lens be moved slightly to the left, the

object will appear to advance toward the right; and, conversely, as the lens is moved toward the right, the object is displaced in the opposite direction. Let the lens be cut in half, transversely, and the two semi-circular pieces reversed as to their former position, i.e., placed side by side, and so that their thin edges shall be adjacent, while the two plane edges, formed by the section of the lens, are kept in mutual parallelism, and have their faces turned outward, toward the left and right respectively: the right eye will now look through the left half of the lens, and *vice versa*; and the two pictures, each placed opposite its appropriate eye, and in the principal focus of the eye-piece, will be seen, not in their actual places, but in a position midway between the two. The subsidiary purposes served by this arrangement are that the pictures are magnified as well as caused to coalesce; and that the equality of the magnifying power of the eye-pieces (a result by no other means certainly attainable) is secured by the fact of their being cut from the same lens, the whole of which is thus advantageously and economically utilized. In too many of the instruments offered for sale the conditions stated above are very imperfectly fulfilled; the parallelism of the two sectional planes of the semi-lenses, and their rectangularity with two imaginary planes joining their opposite ends respectively, are not maintained, and, as a consequence, the coalescence of the pictures is effected, if at all, by a forced and more or less painful displacement of the eyeballs, entirely destructive of all pleasure in the use of the instrument. And it is important to recollect that this parallelism of the sides of the semi-lenses may be either actual or virtual; for to whatever shape they may be cut (and the circular form is the one most often adopted), the foregoing conditions are in nowise altered. The best lenticular form of the instrument with which we are acquainted is the achromatic stereoscope devised by Messrs. Smith, Beck, and Beck, the well-known London opticians, which combines excellencies of a very varied character.

It remains to speak of the pictures in their relation the one to the other as a stereoscopic pair. Evidently, exactly to reproduce the conditions of normal vision, they should be taken from points of view separated laterally by a space equal to the distance between the eyes, viz., about $2\frac{1}{2}$ in.; and for all objects within narrow limits of distance this rule is observed. But taking a wider range, such as would include, for instance, an extensive architectural pile, photographers usually take their pictures from spots separated by a considerable interval; and the stereoscopic slides thus obtained, when viewed in the stereoscope, exhibit effects of solidity or relief of a very striking character. Inasmuch, however, as these effects are due to a gross exaggeration of the ordinary difference of perspective relatively to the two eyes, they to a like extent misrepresent the actual appearance of the scene; and it were to be wished that for all stereoscopic pairs alike, whether representative of near or of remote objects, photographers would be content to adopt that exact relation of the two retinal pictures which subsists in ordinary binocular vision. As to the mounting of the pictures, it is of course highly important that they be placed exactly in the same line; it has further been pointed out by Mr. Claudet that, as the apparent solidity of the objects viewed in the stereoscope conflicts with the evident flatness of the cardboard mount, it is advantageous to adopt the following expedient. The pictures must be of the same size, but instead of having them identically the same as regards the objects represented on each, let the left-hand picture include on its left-hand margin somewhat less than is found on the same margin of the right-hand picture; similarly, let its right-hand margin contain somewhat more than is found on the same margin of the right-hand picture: then will the view appear to extend well out of and beyond the cardboard, which forms, as it were, a framework around it. A moment's consideration will show that this ingenious arrangement does but reproduce the conditions which obtain whenever we look out upon a scene through a casement distant from us by a few feet. Availing himself of the libration of the moon, Mr. Warren De La Rue has obtained lunar stereoscopic photographs, which exhibit that body with a general appearance of rotundity, while the other objects on her surface are seen in conspicuous relief. These effects are, however, evidently due to an exaggeration of the "binocular parallax;" for by no human eyes, how near soever they might be placed to the lunar surface, could such a view be obtained. It is, as sir John Herschel has remarked, as though the moon were seen with the eyes of a giant, placed thousands of miles apart.

Among the minor applications of the stereoscope may be mentioned the STEREOMONOSCOPE and the STEREOTROPE, the former devised by Mr. Claudet, the latter by Mr. William Thomas Shaw; and severally described by them in the *Proceedings of the Royal Society* of June, 1857, April, 1858, and Jan., 1861. In the stereomonoscope, the two pictures of a stereoscopic pair are projected, by means of lenses, on to the posterior surface of a piece of ground glass, one upon the other, or so that they occupy the same place; when the observer, looking from the opposite side of the glass, sees them not as a confused mixture of two pictures, but as a single stereoscopic representation, possessing the usual attributes of solidity or relief. The stereotrope consists in an application of the principle of the stereoscope to that class of instruments variously termed thaumatropes, phenakistoscopes, etc., which depend for their results on "persistence of vision." In these instruments, as is well known, an object represented on a revolving disk in the successive positions it assumes in performing a given evolution, is seen to execute the movement so delineated; in the stereotrope, the effect of solidity is superadded, so that

the object is seen as if in motion, and with an appearance of relief as in nature. A highly ingenious application of the principle of the stereoscope to portraiture has been described by Mr. Henry Swann in the *Report of the British Association for 1863*. In this arrangement, the portrait is seen as a solid bust imbedded in a cube of crystal. A form of the reflecting stereoscope, in which the planes of reflection are vertical, has been proposed by Mr. Walter Hardie. See *ZOETROPE*; Brewster, *The S*.

But by far the most important application of the stereoscopic principle, is its realization in the binocular microscope of Mr. Wenham, the advantages of which over the monocular form of that instrument are increasingly appreciated by microscopists. In this, the right and left eye pictures, respectively, are thus obtained. Immediately behind the object-glass, a small and peculiarly shaped prism is placed in such a position, that it shall receive the whole of the rays coming through the right half of the lens. These rays, after being twice reflected within the body of the prism, finally emerge at such an angle to their original direction, that they cross the undiverted pencil of rays transmitted by the other half of the lens, and are then received into a second tube, which, being inclined to the first or main tube at an appropriate angle, conveys them to the left eye; while the other complement of rays pursues an undeviating course to the right eye. Each of the two tubes is fitted with the usual eye-pieces; and object-glasses of all but the highest powers may be used with pleasure and advantage. For a fuller explanation, see the original paper by Mr. Wenham in the *Transactions of the Microscopic Society*, new series, vol. ix., page 15. See *Helmholtz, Physiol. Optik*; and his *Popular Lectures*.

STEREOTYPING (Gr. *stereos*, fixed, solid), the art of fabricating metal plates resembling pages of type, from which impressions may be taken as in ordinary letter-press printing. The plates, which are composed of type-metal, are about $\frac{3}{16}$ of an inch thick, perfectly smooth on the back, and having a face exactly resembling a page of movable type. To yield an impression, the plates are fastened by a temporary arrangement to blocks of wood—plate and block together being the height of a type, or one inch. Stereotyping is not employed where only a definite and moderate number of impressions of any work are required. Its chief value consists in its availableness for future impressions contingent on the renewed demand for copies; but it is also of importance in duplicating the means of taking large impressions quickly. Considering the small quantity of metal employed in fabricating a stereotype plate, printers are enabled to secure and store up forms of type, so to speak, at a comparatively small outlay, and have at all times the means ready at hand to produce fresh editions without the trouble or cost of setting a single letter. As in the case of many valuable inventions, there has been not a little discussion as to who was the discoverer of the art of stereotyping. By some it has been ascribed to Van der Mey, a Dutch printer, who early in the 18th. c. executed editions of the Bible from forms of fixed type. Van der Mey's process, however, was not stereotyping in the proper sense of the word; for it consisted in nothing more than soldering together all the types in a page in order to fix them permanently. There can be no doubt that the inventor of stereotyping was William Ged, a goldsmith in Edinburgh, who made the discovery about 1725. In 1727 he entered into a contract with a person to prosecute the business of stereotyping; but this person, who had little means, becoming intimidated, the contract was relinquished. In 1729, Ged entered into a partnership for the same object with William Fenner, a London stationer. Afterward, John James, an architect, Thomas James, a type-founder, and James Ged, son of the inventor, joined the partnership. By this association, certain Bibles and prayer-books were stereotyped for the university of Cambridge about 1731. Ged's success was so far complete, but his prospects were blighted by ill-treatment from his partners, as well as by the misconduct of the pressmen employed to print from his plates, which they maliciously damaged and rendered imperfect. The university appears to have at length abandoned the use of the plates, which were sent to Caslon's letter foundry in London to be melted. A few of these plates escaped the crucible, and from two of them, being pages of the Book of Common Prayer, impressions are given in Hansard's *Typographia*, Part II. 1825. Ged's partnership was broken up in 1738, and full of disappointment he returned to Edinburgh. There, he prosecuted his art, and was able to execute several editions of Sallust, of a small size, for the use of schools. Copies of these editions still exist. The earliest which we have seen purports to be printed in 1739, and bears an imprint in Latin which may be translated as follows: "Not executed by movable types, but by tablets of fused metal." The printing is as neatly executed as that of any volume at the period. This Sallust of 1739, as we apprehend, was the first book correctly printed from stereotype plates. To add to the cares of William Ged, his son James engaged in the Jacobite insurrection of 1745, and was taken prisoner, and condemned; his life, however, was spared on account of his father's useful invention, and he proceeded to Jamaica, where William, his brother, was already settled. William Ged, the inventor of stereotyping, died at Edinburgh, Oct. 19, 1749, in very indifferent circumstances.

The art of stereotyping has undergone little change since its discovery by Ged. The process of fabricating plates is very simple. The page of type being set, corrected, cleaned, and fixed in a frame, is laid on a smooth iron table face upward; a little fine oil is brushed over it, to prevent the liquid stucco from adhering; the stucco to the con-

sistency of cream is now poured over the face of the page, and straightened over it in the process of hardening; when hardened, the cake of stucco is lifted off, and is seen to be a perfect mold of the types. The cake is now baked in an oven, and then placed in an iron pan; the pan, which has inlets at the upper side, is plunged into molten metal, which soon runs into the mold; being lifted out and cooled, the pan is opened and found to contain a plate resembling the page of type; the mold is broken and of no further use. When removed from the pan, the plate is rough, and needs to be trimmed for working; for this purpose it passes through the hands of artisans, who prepare it for the press. Should any particular letter be defective, it is dug out, and a corresponding type inserted; the end of which type is cut off at the back of the plate by a soldering bolt. In preparing plates for press, nothing is more important than giving a high degree of level smoothness to the back, and to effect this certain planing and smoothing operations are adopted. Such is the old and well-known *stucco* process of stereotyping. Latterly, there have been divers improvements as regards the shape of the pans, in order to facilitate the fabrication of several plates at once, but the principle is in all cases the same. After the stereotyping is finished, the types are distributed. In some printing-offices, all work whatsoever is executed from plates, and types are employed only to produce molds. This, however, does not save types from deterioration; in cleaning them with brushes and oiling them for the stucco, their finer parts become in no long time rounded off. As regards impressions from stereotype plates, the work is seldom so sharp and fine as from pages of movable letter; but it answers every required purpose in a large variety of cases. Plates properly manufactured, stored, and mended when necessary, will last for repeated impressions to the extent of hundreds of thousands over a long series of years. The stock of plates in some establishments is accordingly large, and represents a considerable sunk capital.

The method of preparation of the stereotype plates used on newspaper printing presses is as follows:

The page forms of type and cuts being lowered from the composing room, each page is at once put upon the molding or beating-table, and covered with fine sheets of a specially prepared paper, then with felt, and passed under a heavy power-driven roller. This forces the paper into every depression of the faces of the types and engravings, making an *intaglio* or "matrix," in which the entire contents of the page can be read from left to right. The form, with its matrix upon it, is then put upon one side of a double steam table, and covered with a thick felt; the platen is brought down with great pressure by a hand-wheel and screw, and held there for about 6 minutes, while the matrix is baked hard at a temperature of about 300° F. After being trimmed square and to size by a knife at the back of the steam table, it is then almost ready for casting; but first any very great depressions in the reverse side of the matrix are generally reinforced with felt backing pieces to enable such places to withstand the pressure of the hot metal. The reinforced matrix constitutes a tough, flexible mold, which is then dusted with French chalk, and next bent around the concave side of a semi-cylindrical casting-box, the outer and inner shells of which are then brought together and clamped firm, so as to leave a space of about half an inch between the face of the matrix and the core of the box. The casting box is balanced upon trunnions and has cold-water circulation, so as to keep it as nearly cool as possible.

The metal furnaces hold from 2500 to 5500 lbs. each of seething molten stereotype metal. Two men with a huge ladle dip out more than enough of the bright, heavy liquid to make a page form, and pouring it with a skillful dash into the casting box, return the ladle, open the clamps, withdraw the hot cast and place it upon the horse of the sawing or cutting-off machine, where it is automatically clamped, and with one hand the operator, with two turns, trims off both ends of the semi-cylindrical cast to exact length and proper bevel. From this machine it is removed and put upon another horse, or finishing cylinder, upon which its sides are planed straight by two men, and any large open spaces cut away to greater depth. It is then dropped into the semi-cylindrical lap of one of the two power-shaving machines, in which a knife sweeps around and reduces the thickness to the standard, leaving the cast with perfect inner surface. Hot as it is, it is rushed to the press-room.

The time employed in stereotyping is about as follows: making the rough matrix from the form, $1\frac{1}{2}$ minutes; under the steam table, 6 minutes; taking cast, $1\frac{1}{2}$ minutes; sawing, 1 minute; routing and side planing, $\frac{1}{2}$ minute; shaving inside, $\frac{1}{2}$ minute; total, $9\frac{1}{2}$ minutes.

The stereotyping department of the N. Y. *World* had (Nov. '89) a capacity to cast and finish 150 page forms per hour. From each supplement matrix there are frequently taken 20 casts, and from each of the main-sheet pages 16, to enable all the presses to run at once upon the last form of the latest edition. Each week-day night there are made about 200 casts, each weighing 80 lbs. gross, or 48 lbs. when finished, making 16,000 lbs. of metal handled. Saturday nights there are required for a 32 page paper 600 plates, weighing, unfinished, 48,000 lbs., or 24 net tons.

As new editions of old newspapers are not wanted, the plates are melted down as soon as the operations of the day are over. Even when books are printed from movable types, it may serve a good purpose to take paper molds from them before distribution; for the molds, on being dried, can be laid aside and be afterward employed for fabricating plates should a new impression be wanted. The author of a book, for example,

could, at a most insignificant addition to the expense of type-setting, possess himself of a set of paper moulds of his work, to be used if necessary at some future period, in order to save the type-composition for a new edition.

STERILIZED FOOD. Food is said to be sterilized when it has been subjected to an agent capable of destroying the germs of fermentation or disease which might be present. The articles of diet not usually treated by heat before ingestion are fresh fruits and certain vegetables, water, and milk. Fresh fruits and vegetables seldom contain any harmful germs, but milk and water are especially favorable media for bacterial development.

Water and Ice.—Water is sterilized by boiling or by distillation. It is then best prepared for table use by putting into sterilized stone bottles, and placing on ice. The addition of ice to drinking water affords an opportunity for the introduction of bacteria into the digestive organs. It has been shown by the researches of Dr. Prudden that the bacilli of various diseases (especially typhoid fever) are not destroyed by freezing, and that certain varieties will retain their vitality even after prolonged imprisonment in ice. Sterilized ice is now manufactured from distilled water.

Sterilized Food.—It has been said that while the adult naturally lives on cooked or sterilized food, the child who does not depend upon the mother's breast, has been left to uncooked, unsterilized food. Milk drawn by the suckling from the mammary gland is practically free from germs; but cow's milk, as offered for sale, at a distance from its source, cannot fail to contain bacteria.

The question of sterilized food becomes then principally the question of sterilized milk.

Milk—Sources of Contamination.—Particles of dirt and manure may fall from the udders during milking, or may come from the dairyman's hands. Impure water used for cleaning cans, even if not used for adulteration, may be the means of contamination. Diseased condition of the animal herself, such as tuberculosis or "foot-and-mouth disease," may furnish germs to the milk. As milk readily absorbs impurities, mere exposure to the air is a possible cause also for contamination. Milk contains the elements of a complete nutrition, and therefore forms a favorable medium for the development of micro-organisms until the reaction becomes changed by the formation of considerable acid. Currier has shown (*milk sterilized*), *N. Y. Med. Rec.*, July 21, 1890, by bacteriological experiment, that milk coming directly from the udder is practically sterile, and that micro-organisms must make their entrance later. A portion of milk was drawn into a sterilized bottle from a healthy cow, whose udder, as well as the dairyman's hands, had been carefully cleansed. A drop was placed on a gelatine plate, which after one week showed no bacteria. The bottle was carefully sealed, and after a week the milk was absolutely unchanged. He then took the same quantity of milk from a grocery shop, receiving it as before into a sterilized bottle, and sealing. In one week this specimen was sour and the caseine had separated. Gelatine plates which three days before had each received a cubic centimetre of this milk, showed a hundred thousand colonies in each.

Bacteria found in Milk.—Jeffries (*Trans. Am. Pediatric Soc.*, 1888-89) has described six varieties of bacteria (in addition to the non-pathogenic *bacillus lactis aerogenes* and *bacterium coli commune* always found in milk fæces whether normal or abnormal), which produce active fermentation in milk. It was found that all the varieties of bacteria found in diarrhœal fæces thrive, and many produce important changes in milk.

- I. Some coagulate milk with acid reaction.
- II. Some render milk acid without coagulation.
- III. Render it alkaline without coagulation.
- IV. Change slightly acid milk into alkaline, and then coagulate it with alkaline reaction.
- V. Causes milk to become a transparent fluid without coagulation.
- VI. Produce above change after first coagulating the milk.

In 1857 Pasteur discovered that the souring of milk was due to the presence of micro-organisms, refuting Liebig's theory that caseine furnished the chemical ferment which caused this change. Since that time there has been constantly increasing evidence also that bacteria that develop in milk can produce ptomaines, which are active poisons. Although but few of the bacteria present in milk affect its nutritive value, still they are not desirable, and if conditions favorable to their activity exist, they may become positively harmful. So sterilization aims to kill all the bacteria in milk which by their development would produce lactic or butyric acid fermentation; besides destroying all other forms which might accidentally be present as the germs of decomposition, supuration, or of specific diseases.

Chemical Sterilizers.—It has been proposed at various times to prevent the development of germs in milk by the addition of harmless antiseptic substances. But it has been found that even with such drugs as salicylic and boric acid, quantities too large to be wholesome must be employed. It has been shown that in milk originally neutral even the feebly vitalized cholera germs remain alive and harmful until the milk has become decidedly acid. Alkaline salts (as well as neutral) favor the activity and increase of bacteria rather than otherwise.

Cold as a Sterilizer.—A low temperature retards development of bacteria for a time, but does not, in some cases, destroy them, even if frozen.

Heat as a Sterilizer.—A temperature of 212° (and in many cases less), maintained for about an hour, can be relied upon to kill all germs. Superheated steam is the most rapidly effective form of the application of heat; boiling water is next; and an even lower degree, 167° F. “*Pasteurization*,” is sufficient for many bacteria. A lower temperature than this will destroy the bacilli of typhoid fever and of cholera; but the tubercle bacillus is more resistant, and requires the full 212° at least twenty minutes.

Apparatus for Sterilization of Milk by Heat.—There are three forms of sterilizers in general use—those of Soxhlet, Arnold, and Seibert. Soxhlet's is on the principle of a bath of boiling water; Arnold's, on that of superheated steam. Seibert's sterilizer claims to be on Soxhlet's principle.

a. *Soxhlet's Apparatus*, first described in Nos. 15 and 16 of the *Münchener Medizinische Wochenschrift*, 1886, consists of a tray holding 10 feeding bottles with combination stoppers, and a pot to boil them in; 6 extra bottles, a tin dipper to warm the milk in before feeding, and a brush for cleansing.

“The bottles are filled within one half inch of the neck. Into each bottle a perforated rubber stopper is pressed. The bottles are placed in the tray, which is set in the pot of water. After the water has come to a boil, and expansion has taken place, the glass stoppers are pressed into the perforated rubber stopper, thus hermetically closing each bottle. The milk remains in the boiling water fifteen to twenty minutes longer, and is for that length of time under pressure in a temperature of 212° F. Milk so prepared will keep sweet four to six weeks. When the milk is to be used, the bottle is put into hot water for a few minutes, until the contents are warm. The stopper is then removed and an ordinary nipple attached. Milk remaining in the bottle after the child has been fed is thrown away.”

b. *ARNOLD'S STERILIZER* (Cheesman, *N. Y. Med. Rec.*, July 13, 1889) depends upon superheated steam. This form of apparatus is the one most generally used. The bottles, which are made rounded and without necks, having no angles, are stopped with a wad of cotton, and placed upon a rack within the oven.

A. Shallow Copper Steam Generator. B. Reservoir or Pan. C. Steam Funnel. D. Sterilizing Chamber. E. Hood. “Water is poured into the pan or reservoir, whence it passes slowly through three small apertures into the shallow copper vessel beneath,

becomes converted into steam, and rises through the funnel in the centre of the sterilizing chamber above. Here it accumulates under moderate pressure at a temperature of 212° F. The excess of steam escapes about the cover, becomes imprisoned under the hood, and serves to form a steam jacket between the wall of the sterilizing chamber and the hood. As the steam is forced down from above and meets the air, it condenses and drips back into the reservoir. It will generate steam from cold water in three or four minutes on an ordinary fire—coal, gas, or kerosene. The time required for sterilizing milk in the Arnold apparatus is 30 to 45 minutes."

c. SEIBERT'S METHOD was designed to meet the wants of the poorer classes whose means could not compass the Arnold or Soxhlet apparatus. Dr. Seibert (*N. Y. Med. Jour.*, Feb. 15, 1890) devised a tray with bottles of rounded corners, no necks, and so shaped that a lead-pencil will reach any part. This tray can be set into an iron kettle such as is found in any household. The tray is made to fit a pot 10 in. wide and 8 in. high. The bottles are filled partly full of milk up to a mark blown into the glass, which varies according to the age of the child, and are then filled to the top with barley or oatmeal gruel or plain water. The bottles are closed by a rubber stopper having a groove on the side by which steam escapes. This groove does not reach to the top of the cork, so that by giving it a turn on removal the bottle can be completely closed. The tray with the bottles is set into the kettle, which contains 2 teacupfuls of water. The lid is put on and the steaming continues for 30 minutes in cold weather, for 45 in warm.

Effect of Prolonged Heat upon the Ingredients of Milk.—Chapin found that heat applied long enough to sterilize milk produced an appreciable effect upon the caseine, the fat, and the albumen. The caseine coagulates in smaller clots, but still is much tougher and less digestible than human caseine. The fat is collected in larger globules, and may be often noticed in nursing bottles as flakes. The albumen is partially or completely coagulated.—*N. Y. Med. Rec.*, June 21, 1890.

Diseases propagated through Unsterilized Milk.—Typhoid fever, tuberculosis, scarlet fever, cholera, and diseases of the digestive tract (especially the summer diarrhoeas of infancy) are the diseases most likely to have their germs conveyed by milk. With the sterilization of milk came a revolution not only in infant feeding in health, but also in the course, treatment, and fatality of summer diarrhoea of young children. The germs of typhoid fever are supposed to get into milk through water used for adulteration and to rinse the cans. The micro-organisms are very susceptible to heat. The tubercle bacillus may be present in milk, coming from the mammary gland of the cow, or entering through some outside source of contamination. Primary tuberculosis of the digestive tract occurs from ingestion of the tubercle bacillus. This is comparatively rare, but there are cases on record.—*Northrup, Am. Jour. Med. Sc.*, Sept. 1890. *Bang, Copenhagen Congress*, 1884).

The identity of the "foot-and-mouth disease" in cattle, and scarlet fever in the human subject, is still questioned, but the study of a remarkable epidemic in Dover, England, in 1885, certainly points to a close relation, as well as to the transmission of disease by milk. It was noticed that an epidemic sore throat in a certain village followed the route of a particular milkman. On inquiry it was found that at the farm from which this milk came the cows were affected with the foot-and-mouth disease. An elaborate investigation practically established the fact that the milk of cows suffering from this disease would produce a sore throat resembling scarlet fever. Subsequently this same locality was visited by an epidemic of true scarlet fever, and no individual who had previously had this sore throat was attacked.—(Stickler, *N. Y. Med. Rec.*, Sept. 13, 1890).

Such cases as these, of which there is clear proof, are sufficient to show that an unknown danger lurks in every specimen of unsterilized milk, unless very recently drawn from a cow known to be sound and clean into vessels known to be aseptic.

STERLET. See **STURGEON.**

STERLING, an epithet generally applied to the money of the United Kingdom. The original standard of money was weight, and among the Anglo-Saxon and Teutonic nations the basis of weight was in early times supplied by the wheat-corn. Charlemagne superseded the earlier systems by a new coinage, in which a pound of 12 ounces became the money weight, each pound being divided into 20 solidi, and each solidus into 12 denarii of the weight of 32 wheat-corns. The older *sifer* or scruple of 24 wheat-corns being superseded by the penny of 32 wheat-corns, the term *sterling* seems to have been applied to the latter, in consequence of its being in use among the Ripuarian or Austrasian Franks, sometimes called the *Esterlings*, while the old scruple continued to be used by the Northmen. In England where the change was early introduced, the word *sterling* came in the course of time to indicate the fineness or standard of the silver; and nearly the same standard, consisting of 11 oz. 2 dwt. of pure silver, and 18 dwt. of alloy to the pound troy, or $\frac{18}{32}$ dwt., seems to have subsisted from the 12th c. downward. The superiority of the English standard silver to all other currency has been generally acknowledged over Europe; and hence the adjective *sterling* has become a synonym for pure and genuine.

STERLING, a co. in central S. Dakota, formed in 1883. It is drained by the Cheyenne river; 1185 sq. m.; unorganized; pop. '90, 96.

STERLING, a city in Whiteside co., Ill.; on the Rock river, and the Chicago and Northwestern and the Burlington Route railroads; 110 miles w. of Chicago. It has electric lights, waterworks supplied from artesian wells 1600 feet deep, about 15 churches, national banks, daily and weekly newspapers, a railroad and a highway bridge across the river, Sterling and Wallace high schools, Lincoln school, and public library. The principal industries are farming and manufacturing, for which there is good water-power. Pop. '90, 5824.

STERLING, JOHN, 1806-44; b. Scotland; educated at Glasgow and Cambridge. He was for a time connected with the London *Athenæum*. He took orders in the English church, but after a short service as a curate, devoted himself entirely to literature. Among his writings are *Arthur Coningsby* (1833); *Poems* (1839); *The Election*, a poem (1841); and *Strafford*, a drama (1843). He is more celebrated from Carlyle's *Life of John Sterling* (1851), than from his own works. A memoir of him, with 2 vols. of *Essays and Tales* was published by J. C. Hare in 1848.

STERNBERG, a t. of Austria, in Moravia, 12 m. n.n.e. of Olmütz. Pop. '90, 15,395. It was founded in the 13th century by Jaroslav von Sternberg, who defeated the Mongols here in 1241. It has an old church, ruined castle, a weaving school, insane asylum, large tobacco houses, silk works, dye works, and trade in leather. It is the chief seat of the Moravian cotton manufactures, and has also not unimportant manufactures of linen, hosiery, and liquors. The cotton and linen goods made at Sternberg, and in the vicinity, are known as *Sternberg wares*.

STERNE, LAURENCE, though of English descent and parentage, was born at Clonmel, in Ireland, on Nov. 24, 1713. In that country also, in some intermittent way, a good deal of his boyhood was passed with possibly some effect in developing that oddity and whimsical exuberance long after to find vent in his writings. His father was of a good Yorkshire family, and as lieutenant in a marching regiment led a wandering and unsettled life. When about ten years old, the boy was consigned to the care of his kinsman, Mr. Sterne of Elvington, in Yorkshire, by him put to school near Halifax, and thence, on his approving himself a lad of parts, transferred, in 1733, to Jesus college, Cambridge, where, in 1736 and 1740 respectively, he took the degrees of bachelor and master of arts. He was educated for the church, and on his leaving the university, his uncle the Rev. Jacques Sterne, an ecclesiastical dignitary of some magnitude, procured for him the living of Sutton in Yorkshire. With this relative he afterward quarreled, but not before another appointment had been secured him as prebendary of York cathedral. In 1741, he was married to a lady whom he met in York, and soon after, through the influence of a friend of his wife, he was presented to the additional living of Stillington. For nearly 20 years he lived at Sutton unheard of. That his devotion to his clerical duties was great, is more than can be supposed from what we know of his character; and we can readily believe the "books, painting, fiddling, and shooting," which he tells us were his choice recreations, formed pretty much the business of his life. Up to the year 1759, in which the first two volumes of his *Tristram Shandy* appeared, he had published only two sermons, which, according to his own statement, "found neither purchasers nor readers." *Tristram Shandy*, which, though published without his name, was from the first known to be his, had instant and immense success, and Sterne, on going up to London, found himself the literary lion of the day. In 1761, two more volumes of it appeared, followed by vols. 5 and 6 in 1762, vols. 7 and 8 in 1765, and in 1767 by the 9th and last. During this period he also issued 4 vols. of sermons, and the *Sentimental Journey*, published in the beginning of 1768, completes the list of his works. He died on March 18 of that year, his health having been much impaired for some considerable time.

From the time of his becoming famous his parishioners saw of Sterne but little. He lived mostly either on the continent or in London, where his literary celebrity made him welcome in the best circles. Always an easy, mercurial kind of mortal, he now led some-

what a gay and dissipated life, rather modelled on the epicurean maxim of enjoying the present hour, than on those more serious precepts he had been wont to enforce from the pulpit. But except that he does not seem to have been excessively devoted to his own wife—she and her daughter being in these pleasant years but little with him—and was a little of a sentimental Lothario in respect of the wives of other people, no very great harm is known of him. He is said, despite of the exquisite sentiment which abounds in his writings, to have been really heartless, and unfeeling; and the sneer of Walpole that he could snivel over a dead ass, to the neglect of his live mother, is familiar to almost every one. It is in fairness, however, to be said that the implied slander rests on no distinct basis of evidence.

Whatever question may be made of the worth of Sterne as a man, there can be none of his genius as a writer. *Tristram Shandy*, his chief work, must live as long as the language, were it only in virtue of the three characters of Old Shandy, Uncle Toby, and Trim, the most perfect and exquisite, perhaps, in the whole range of British fiction. These are genuine creations, at once fantastic and real, in which the subtlest reconciliation is effected between the sportive exuberance of fancy and the sober outlines of truth. Otherwise there is a good deal in the work which needs excuse; in particular a most willful and gratuitous indecency almost without a parallel, and a constant trick of lawless and whimsical digression, to the endless incalculable frivolities of which even the inimitable grace, ease, and tricky flexibility of the style can with difficulty reconcile the reader. The humor of Sterne is notwithstanding the most subtle, airy, delicate, and tender to be found in our literature; and in many passages he shows himself master of a pathos equally exquisite and refined. The fullest, and in every way, best account of Sterne will be found in his *Life*, in 2 vols., by Mr. Percy Fitzgerald, published in 1864. Though against the charge of unclerical levity, at once in his writings and his life, it is impossible to defend Sterne, except as the laxer *morale* of his time may afford some slight palliation of it, candid investigation suggests a more kindly view of his character than that formerly current. See Traill's *Sterne* (1882).

STERNHOLD, THOMAS, one of the authors of the English version of psalms formerly attached to the book of common prayer, was a native of Hampshire, and born toward the close of the 15th century. He held the office of groom of the robes to Henry VIII. and Edward VI., and died in 1549. At the reformation period, when the practice of singing metrical psalms—first introduced by Clement Marot among the gay courtiers of Francis I.—was taken up by the reformers, Sternhold undertook to render the whole book of psalms into English verse. He only lived to complete twenty-one psalms; and his version was published after his death under the title of *All such Psalm of David as Thomas Sternhold did in his Lyfe drawe into English metre* (Lond. 1549). Sternhold's labors were completed by John Hopkins and William Whittinghame, and first annexed to the book of common prayer with the music attached, as *The Whole Booke of Psalmes, collected into English metre by Thomas Sternhold, John Hopkins, and others; compared with the Ebrue, with Notes to sing withal*. Sternhold's and Hopkin's songs are very literal, but somewhat coarse and homely in phraseology. They were used in the church service of England till superseded by the version of Tate and Brady, which appeared in 1698. They were also in use in Scotland down to the middle of the 17th century.

STERNIDÆ. See **TERN**.

STERNUM, a portion of the skeleton of animals. It is present in the articulates (arthropoda) and crustaceans, as well as arachnides and insects, and in those vertebrates having exoskeletons, as tortoises, although Mivart and many others hold that the plastron does not form (or contain) a sternum—in other words, that the chelonians are sternumless. A true sternum, however, belongs to the warm-blooded vertebrates, and reaches its highest development in the birds. The somites of locusts have well-developed sternal sections included between the pleura or side portions of the segments, especially in the abdomen. All these sternal sections are collectively called the *sternum*. It can, however, be said to be only analogous to the mammal sternum, or the sternum of birds. It has nearer relations to the sternal pieces of the tortoises, because the plastron which these pieces constitute is a part of the exoskeleton, and, as above mentioned, is by many not regarded as a true sternum. In some mammals, and especially in man, there might seem to be more analogy (if analogies are to be strained) between the sternum and the "exoskeleton sternum," than between this latter and the sternum of birds, for in them the relations with the rest of the endoskeleton are much more extensive. Man's sternum is little else than a point of attachment for certain pleural pieces, the ribs and rib cartilages, and a covering or shield for the central part of the thorax. In the chelonians the whole of the under shell, or plastron, is regarded by some as a sternum, and composed of pairs of pieces, and one single piece, the *entosternal*. The pairs are the *episternals*, the most anterior, arched portion of the plastron, and including within the arch the *entosternal*; the *hyosternals* and *hyposternals*, respectively anterior lateral and posterior lateral, and not joined together as pairs in the median line. Posteriorly, and joined together at their extremities, are the *xiphisternals*, small curved pieces, forming an arch, like the anterior episternals. In birds of flight the sternum is the most important bone in the body; it is enormously expanded, and gives attachment to the powerful pectoral muscles which move the wings. In birds of great powers of flight it extends

over the abdominal cavity, and sometimes reaches the pelvis. In all birds which fly it has a median ridge, called the keel, which is prominent in proportion to the powers of flight, examples of which are seen in the sternum of the pigeon, the duck, and the wild goose. In ostriches and other birds which do not fly the sternum has no keel. In the mammalia it is composed of several pieces, usually three, the *manubrium*, or anterior portion, the *mesosternum*, or middle portion, and the *xiphisternum*, or posterior portion (in man, xiphoid cartilage). In most mammals the sternum is long and narrow, but in some, as in cetacea, it is broad. The Greenland whale has only a manubrium, while the dugong has this piece and the xiphisternum, the mesosternum being absent. In some mammals, burrowing and flying animals, as the moles and bats, the sternum has a keel, but it is placed differently than in birds, being more anterior. The middle and posterior parts of the sternum in birds are those which are most developed, the manubrium being greatly subordinate or dwarfed.

STERNUTATORIES, are agents which cause sneezing. The most common are the different kinds of snuffs, but other substances are known which produce a more powerful and prolonged action on the nasal mucous membrane. They have been employed in medicine with various objects; as, for example, to restore suspended respiration in cases of fainting, to dislodge foreign bodies from the nasal passages or even the wind-pipe, to avert or check hysterical attacks, and to terminate prolonged fits of hiccup. They are scarcely ever used at the present day.

STESICHORUS, lived about 570 B. C.; b. Sicily; a Greek lyric poet, a contemporary of Pittacus, Alcæus, and Sappho. It is said that he was educated at Catana and afterwards became the friend of Phalaris, tyrant of Agrigentum, but the accounts of his life are mere matters of tradition and consist largely of fables, as illustrated by the story that he was struck with blindness on account of writing against Helen, but recovered his sight after he had published a recantation. His original name was Tisias, and that of Stesichorus (leader of choruses) was given him from his main employment; he is said to have invented the tragic chorus. He excelled in the arrangement of the strophe, antistrophe, and epode, which were called the "three things of Stesichorus." Of his odes, poems, and hymns but a few fragments remain. These consist of fables, elegies, a pastoral poem, *Daphnis*, mythical poems, hymns, encomia, pæans, epithalamia and erotic poems.

STETHOSCOPE, THE (Gr. *stethos*, the chest, and *skopeo*, I look into), is an instrument invented by Laennec for examining the sounds of the chest. The upper part is the chest end, the lower the ear-piece. The most convenient measurements are—length, 7 in., diameter of the ear-piece, 3 in., circumference of shaft, 1½ in., and diameter of chest end, 1½ in. The main object of the stethoscope being to circumscribe and localize the sounds which it transmits, the chest end should be small, in order to determine the exact seat of the greatest intensity of sound. To ascertain this, the instrument should be moved right and left, up and down, till its end is on the exact spot from which the abnormal sound for which we are searching—or, it may be, the absence of sound—proceeds. In the construction of the stethoscope, the following points should be attended to: 1. It should be composed of a material which allows the least amount of sound to be lost, and which least of all modifies or prevents the sound. A porous wood, such as cedar or deal, answers these conditions best, a dense wood, like ebony, having a tendency to modify the sound; 2. It should be of one piece of wood, and not, for example, part ivory and part cedar; 3. The ear-piece should be large and flat to secure perfect apposition and occlusion, and the chest end should be narrow and smoothly rounded over the edge. The various sounds heard through the stethoscope are described in the articles **RESPIRATORY SOUNDS**, **PNEUMONIA**, etc.

STETTIN, an ancient town of Prussia, capital of the province of Pomerania (*Pommern*), situated on both banks of the Oder, quite close to the Stettiner-Haff, 83 m. n.e. of Berlin, with which it is connected by railroad. The entire population, in 1895, was 140,724. The district on the right bank of the river was formerly the suburbs of Lastadie and Silberweisse, and is connected with the left bank by four bridges, including a handsome railway drawbridge. The site of the town is hilly, and consequently the streets are uneven, but the houses are good and the environs are very pleasant. The principal buildings are the old castle, or *Schloss*, dating from 1577, the exchange, military casino, and the theatre. Stettin is the most important manufacturing place in Pomerania, the staple industries being sugar refining, machine-making, and the manufacture of chemicals, perfumery, soap, candles, chocolate, etc. There is also a large iron foundry, where all the anchors of Prussian ships are forged. Corn and spirits are largely exported. The commerce of the city is extensive and increasing. Next to Dantzic it is the most important commercial harbor in the kingdom, although accessible only to small vessels. Stettiner-Haff is formed by an expansion of the river Oder n. of the town, and is nearly quite shut in from the Baltic, having communication with the sea only by three narrow straits, the most important of which is the Swine. See **SWINE-MÜNDE**. Of the two projected canals between the harbor and the Baltic, to be built at the expense of the city, one was begun in 1894 and is almost completed. Stettin, the

ancient *Sedinum*, later *Stettinum*, is of Slavic origin, became a flourishing commercial town in the middle ages, joined the Hansa, and was frequently the residence of the dukes of Pomerania, until they became extinct in 1637. It belonged to Sweden from 1648 until 1720, and since then to Prussia.

STEBEN, a co. in extreme n.e. Indiana, adjoining Michigan; drained by Pigeon river and several creeks; traversed by the Lake Shore and Michigan Southern railroad, 330 sq. m.; pop. '90, 14,478, chiefly of American birth. The surface is diversified by lakes and forests, and the soil is fertile; wheat, corn, oats, hay, and pork are the staples. Co. seat, Angola.

STEBEN, a co. in s.w. New York, adjoining Pennsylvania; drained by the Chemung, Tioga, and Conhocton rivers; crossed by the Erie, the Delaware, Lackawanna and Western, and the Fall Brook railroads; about 1490 sq. m.; pop. '90, 81,473, chiefly of American birth. The surface is uneven. The soil is fertile. The principal productions are wheat, corn, buckwheat, barley, wool, and tobacco. There are many saw mills and flour mills. Co. seats, Corning and Bath.

STEBENVILLE, city and co. seat of Jefferson co., O.; on the Pennsylvania Co.'s, the Pittsburg, Cincinnati, Chicago, and St. Louis, and the Wheeling and Lake Erie railroads; 43 m. w. of Pittsburg, Pa. A fort named in honor of baron Steuben was erected here about 1786; the town was laid out in 1798; the city was chartered in 1851; and the area was increased in 1871. The city is built on high land overlooking the river, is the centre of a fertile agricultural region, and is in the vicinity of rich bituminous coal mines. There are natural gas and electric light plants, waterworks supplied from the river, excellent drainage, electric street railroads, about 20 churches, several national and private banks, high school, public school and Odd Fellows' public libraries, female seminary, and daily and weekly newspapers. The chief industries are coal mining and manufacturing, the last including blast furnaces, rolling mills, steel works, glass works, white ware pottery works, and machinery, boiler, flour, paper, fire and paving brick, and sewer pipe plants. Pop. '90, 13,394.

STEBEN, **FREDERIC WILLIAM AUGUSTUS**, Baron, a general of the American revolutionary army, was b. at Magdeburg, Prussia, Nov. 15, 1730; educated at the Jesuits' colleges of Niesse and Breslau; and at the age of fourteen served as a volunteer under his father at the siege of Prague. In 1747 he was appointed cadet of infantry, and in 1758 had risen to the rank of adjt.gen. He was wounded in the battle of Kunersdorf, and in 1761 was conducted as a prisoner of war to St. Petersburg, but was shortly after released. The following year he was appointed adjt.gen. on the staff of the Prussian king, effected important reforms in the quartermaster's department, and superintended an academy of young officers selected for special military instruction. At the close of the seven years' war, he traveled in Europe, and was appointed grand marshal and general of the guard of the prince of Hohenzollern-Hechingen. Being on a visit to Paris in 1777, where the cause of the American rebellion was favored by the government, he was invited by count St. Germain to go to America. He arrived at Portsmouth, Virginia, Dec. 1, 1777, and offered his services to Gen. Washington, which were joyfully accepted; and he joined the army, then in the most deplorable condition, at Valley Forge. He was appointed inspector-general, prepared a manual of tactics for the army, remodeled its organization, and improved its discipline. He was one of the officers who composed the court-martial at the trial of Maj. André. In the campaign of 1780 he had a command in Virginia, and was on the staff of Gen. Lafayette at the siege of Yorktown. As generous in character as he was capable as an officer, he spent his whole fortune in clothing his men, and gave his last dollar to his soldiers. Congress made tardy reparation, and in 1790 voted him an annuity of \$2,500, and a township of land in the state of New York, both of which he divided with his fellow-officers. He died on his estate near Utica, N. Y., Nov. 28, 1794. See Sparks's *American Biography*, and a life by Friedrich Kapp (New York, 1860).

STEBEN, a former co. in Dakota, formed in 1873 from part of Buffalo; subsequently divided between Ward and McLean cos., N. Dakota. Pop. '90, 16.

STEBEN, a co. in s.w. Kansas, intersected by the Cimarron river; 728 sq. m.; pop. '90, 1418, chiefly of American birth. The surface is undulating and the soil is fertile. It has Oklahoma for its s. boundary. Co. seat, Hugoton.

STEBEN, a co. in w. Minnesota, intersected by the Great Northern railroad; 576 sq. m.; pop. '90, 5251, chiefly of American birth, with colored. It is drained centrally by the Pomme de Terre river. Its surface is hilly; the soil is fertile, producing grain and potatoes, and furnishing excellent pasturage. Co. seat, Morris.

STEBEN, an extensive co. in n. Washington, having the boundary line of British Columbia for its n. border; 6194 sq. m.; pop. '90, 4341, chiefly of American birth, with colored. It is bounded on the east by the state of Idaho, and on the w. by the Cascade range of mountains. It is drained by the Columbia river, Clark's Fork, and the Okanagon river; also by lake Osoyoos in the n., and lake Chelan in the extreme s.w. Its surface is mountainous in the w., and in the e. is composed of barren plains relieved by tracts of prairie land of great fertility, producing grain and potatoes, and furnishing good pasturage. Gold is among the mineral products. Co. seat, Colville.

STEVENS, ABEL, D.D., b. Philadelphia, 1815; educated at Wesleyan university, Middletown; settled pastor of a Methodist church in Boston, 1834; traveled in Europe, 1837; returning, was stationed at Providence, R. I.; became editor of *Zion's Herald*, Boston, 1840; *National Magazine*, New York, 1853-4; revisited Europe, 1855; edited *Christian Advocate and Journal*, 1856; co-editor of the *Methodist*. He has published *Memorials of the Introduction of Methodism into New England*; *Memorials of the Progress of Methodism in the Eastern States*; *Church Polity*; *The Preaching required by the Times*; *The Great Reform*; *History of the Methodist Episcopal Church in the United States*, 4 vols.

STEVENS, ALEXANDER HODGDON, LL.D., 1789-1869; b. New York; graduated in 1815 at the university of Pennsylvania; became surgeon in the New York hospital; from 1825 to 1837 he was professor of surgery in the College of Physicians and Surgeons of New York; from 1837 to 1839 professor of clinical surgery; and from 1841 to 1855 president of the college. He was made president of the medical society of the state of New York in 1848.

STEVENS, ALFRED GEORGE, 1817-75; b. England; studied art in Italy, 1833-42. On his return to England he devoted himself especially to decorative art, such as wood and marble carving and the painting of ceilings and panels. His greatest work was the modeling of the Wellington monument in St. Paul's, which was not completed at the time of his death.

STEVENS, EBENEZER, 1751-1823; b. Boston. He was active in the agitation which led to the revolution and was one of the celebrated "tea party" of 1773. In 1775 he was commissioned lieut., raised two companies of artillery and one of engineers, and accompanied them to the siege of Quebec. He had command of the artillery at Ticonderoga and Stillwater, and in part at Yorktown. He also served with Lafayette in Virginia. In 1814 he took part in the defense of New York.

STEVENS, EDWARD, 1745-1820; b. Va.; col. of the 10th Virginia regiment in the revolutionary war, through which he served with distinction, attaining the rank of brig. gen. He was afterward long a member of the Virginia senate. He enjoyed the confidence of Washington.

STEVENS, EDWIN AUGUSTUS, 1795-1868; b. N. J.; established, with his brothers, lines of steamboats on the Hudson and several other rivers; and introduced various improvements in machinery and naval architecture. He endeavored, at the beginning of the civil war, to induce the government to make use of the iron-clad vessel begun by Robert L. Stevens, but the offer was declined. He left in his will \$1,000,000 for the completion of the vessel, but that amount was not sufficient, and it was sold to the United States navy in 1874, by the state of New Jersey, to which it had been bequeathed. Congress, however, neglected to make the appropriation, and the vessel was sold in 1880 for a very small amount. Mr. Stevens endowed the Stevens High School at Hoboken, and left nearly \$1,000,000 to found the Stevens Institute of Technology.

STEVENS, HENRY, b. Vt., 1819; graduated at Yale college, 1843, and Cambridge law school, 1844. He resided in London after 1845 for the purpose of purchasing rare and valuable books, and added largely to the collection of American books in the British museum, procuring many valuable works for the Smithsonian institution, the library of congress, and other libraries in the United States. Among his publications are *Catalogue Raisonné of English Bibles*; *Catalogue of American Books in British Museum*; *Bibliotheca Americana*; *Bibliotheca Historica*. He d. 1886.

STEVENS, ISAAC INGALLS, 1818-62; b. Mass.; graduated at West Point, served through the Mexican war, was principal assistant at the U. S. coast survey office, 1849-53, when he resigned from the army to become governor of Washington territory, from which he was delegate to congress, 1857-61. He was a maj. gen. of volunteers in the late civil war, and was killed at Chantilly, while leading a charge.

STEVENS, JOHN, 1749-1838; b. N. Y.; a competitor with Fulton in the building of steamboats, experimenting in their manufacture for nearly 30 years, the sight of John Fitch's steamboat being the incentive to his ambition. In 1804 he built a screw propeller, and afterward the *Phoenix*, with sectional boilers and high-pressure condensing engines, which was completed soon after Fulton's *Clermont*. Fulton had the exclusive right to navigate the Hudson, so Stevens contented himself with the Delaware and Connecticut rivers. He designed, in 1812, a circular iron-clad, similar to those now in the Russian navy, and published a pamphlet setting forth the advantages of railway travel, and suggesting the construction of a railway from Albany to lake Erie. He made the plans for the Camden and Amboy railroad.

STEVENS, JOHN AUSTIN, 1795-1874; b. N. Y.; educated at Yale, and went into business. He was one of the first members of the New York chamber of commerce, of which he was for many years secretary. He was president of the bank of Commerce, 1839-66, the first president of the merchant's exchange, which he helped to establish, and during the war president of the associated banks of New York, Boston, and Philadelphia; and the loans made by them to the U. S. government were made under his direction, as chairman of the treasury note committee. His opinion on financial subjects was much sought for at the treasury department. Though a whig, he was in favor of free trade.

STEVENS, PHINEHAS, b. Sudbury, Mass., 1707; d. 1756, removed with his father to Rutland, New Hampshire. At 16 he was taken prisoner and carried to Canada. He joined in an expedition against Canada, 1746, and gallantly defended his station in Charlestown, on the frontier, from the French and Indians in 1747. In acknowledgment of his bravery he received a valuable sword from Commodore Knowles, and was commandant of the fort until 1750. In the *New Hampshire Hist. Colls.*, v. 199, is an account from his pen of his expedition to Canada in 1749.

STEVENS, P. F., D.D., b. Fla., 1830; graduated at the State military acad., Charleston, S. Car., 1849; was ordained deacon in the Prot. Epis. church, 1861, and presbyter, 1863. Joining the Ref. Epis. church, he was consecrated bp., at Philadelphia, 1879. Bp. S. has jurisdiction over the special missionary district of the South, and is stationed at Charleston, S. Car.

STEVENS, ROBERT LIVINGSTON, 1787-1856; b. N. J.; son of John Stevens; had charge of his father's steamboat, the *Phoenix*, in its passage to the Delaware. In 1808 he introduced concave water lines in the hull of the *Phoenix*, which was the first application of the wave line to shipbuilding. He invented in 1813 percussion elongated shells for smooth-bore guns, and sold his invention to the government. In 1818 he burned anthracite coal in a cupola furnace, using it soon afterward in his steamers. In 1822 he substituted the skeleton wrought-iron working beam for the heavy cast-iron one before in use; and introduced many other improvements in navigation and steam machinery. He was commissioned by the government in 1842 to build an iron-plated war steamer or battery, to be shell-proof and driven by screws, but he died before it was completed.

STEVENS, THADDEUS, 1792-1868; b. Vt.; graduated at Dartmouth college, 1815; taught school in York, Penn., and studied law; began practice in Gettysburg; removed to Lancaster, 1842. In the presidential campaign of 1828 he opposed Jackson, and from that time on was an active member of the whig party. He was first elected to congress in 1848. Previous to this time he had served in the state legislature and as canal commissioner, 1838. He was already an opponent of the slave system, and in the two terms from 1848-52, vigorously attacked the fugitive slave law, the Missouri compromise, and the Kansas-Nebraska bill. From 1852 to 1858 he occupied himself with professional work; in the latter year was again elected to congress, and held his seat until the time of his death. He was chairman of the committee of ways and means for three sessions, and of the "reconstruction" committee of the 39th and 40th congresses. In the impeachment of President Johnson he acted as chairman of the board of managers. The issuing of the emancipation proclamation by President Lincoln and the adopting of the 14th amendment were measures earnestly advocated by Mr. Stevens.

STEVENS, WILLIAM BACON, D.D., LL.D., b. Bath, Me., 1815; educated at Phillips acad., Andover, Mass., and in the medical department of Dartmouth coll.; practised medicine in Ga., and was appointed historian of that state. He relinquished his profession for the study of theology, and was ordained deacon in the Prot. Epis. church, 1843; ordained priest, 1844; rector of Emmanuel church, Athens, Ga., and St. Andrew's church, Philadelphia. He was consecrated asst. bp. of Penn., 1862, and, upon the death of Bp. Potter assumed the full episcopal charge of the diocese. Bp. Stevens, who was for a time prof. of belles-lettres in the univ. of Georgia, had written extensively upon religious and controversial topics, his principal works being *Parables of the New Testament practically Unfolded*, and *Consolation, The Bow in the Cloud*. He also compiled a history of Ga. He d. 1887.

STEVENS INSTITUTE OF TECHNOLOGY, at Hoboken, N. J. A school of mechanical engineering founded by Edwin A. Stevens, who left for it in his will \$650,000, and a block of ground. Annual income about \$81,000. It has fitted large numbers of young men for responsible positions in various industrial pursuits such as machine shops, electric works, motive power of railroads and the like. The course is for four years, and includes instruction in mathematics, physics, general and analytical chemistry, mechanics, mechanical engineering, mechanical drawing, engineering practice, general and applied electricity, experimental mechanics and shop-work, applied mathematics, belles-lettres and modern languages. Extensive workshops are provided, equipped with all varieties of machine tools, steam engines, etc., and in addition there are a large collection of all forms of prime motors, such as steam, gas and air engines, compressors, pumps, and other machinery, with which instruction is given in conducting all sorts of tests as to the power and economy of such machines. This department of experimental mechanics has been and is a leading feature of this institution. In addition to its original endowment, the institute has received at various times contributions from its president, Henry Morton, PH.D., amounting in the aggregate to between \$50,000 and \$60,000, and recently from Mrs. E. A. Stevens, widow of the founder, real estate valued at \$30,000. The institute possesses a good library of works of reference and scientific journals. Number of instructors in 1896, 22; students, 254.

STEVENSON, ADLAI EWING, was born of Scotch-Irish ancestry in Kentucky in 1835, and received his education at Centre College, Danville, Ky. He began the study of law in Bloomington, Ill., in 1858, and after being admitted to the bar, commenced practice in Matamora, but returned to Bloomington in 1869, where he still resides. He was elected to congress in 1874, and re-elected in 1878; appointed First Assistant Postmaster-General 1885-89; Vice-President of the United States in 1892-97.

STEVENSON, JOHN JAMES, geologist, born New York, October 10, 1841, was graduated at New York university in 1863 and 1867, and became professor of chemistry at West Virginia university in 1869. He has been professor of geology in New York university since 1871. As geologist on the Ohio and Pennsylvania surveys, he classified the upper coal measures of those states; and while chief geologist of the U. S. geographical surveys w. of the 100th meridian, described the coal area of New Mexico and southeastern Colorado. He is correspondent of the more important geological societies of the world, and is president of the New York academy of sciences as well as vice-president of the geological society of America. Princeton university conferred LL.D. upon him in 1893. The titles of his published books and papers number more than one hundred.

STEVENSON, ROBERT, a Scotch engineer, was born at Glasgow, June 8, 1772. His father, who was a merchant connected with the West India trade, died during his infancy; and his mother having (1786) married Mr. Thomas Smith, the first engineer of the light-house board, young Stevenson was led to devote himself to the study of engineering, in which his progress was so rapid that in 1791 he was intrusted by Mr. Smith with the erection of a light-house on Little Cumbrae. In 1796 he succeeded his father-in-law as engineer and inspector of light-houses; and during his 47 years' tenure of that office, he planned and constructed no fewer than 23 light-houses round the Scottish coasts; employing the catoptric system of illumination, and his valuable invention of "intermittent" and "flashing" lights. The most remarkable of these erections was that on the Bell Rock (q.v.), for which he had been sketching plans for some time, when the wreck of the *York*, a 74-gun ship, on this reef drew general attention to the same subject. The enterprise was quite unprecedented in light-house engineering, for in the only instance at all analogous—the Eddystone light-house—the rock was barely submerged at flood, while the Bell Rock was never uncovered except at very low ebb tides. In 1814, Stevenson was accompanied in his tour of inspection by sir Walter Scott, and while the former was projecting another light-house on the Skerryvore (q.v.) near Tiree, the latter was doubtless laying up ample materials for those minute descriptions of the w. coast of Scotland and its islands which were afterward embodied in the *Lord of the Isles*. Stevenson was also in great request as a consulting engineer in the matter of roads, bridges, harbors, canals, and railways, introduced many improvements in their construction, and occasionally co-operated with Rennie, Telford, and others. He died in Edinburgh, July 12, 1850. Like most eminent practical men, Stevenson has left few literary remains; these being merely four volumes of professional printed reports, a large work on the Bell Rock light-house, some articles in the *Encyclopedia Britannica*, and in the *Edinburgh Encyclopedia*, and a series of letters. See his *Life* by his son (1878).

STEVENSON, ROBERT LOUIS BALFOUR, Scotch author; b. Edinburgh, 1850; was graduated at Cambridge univ.; studied law, but abandoned law for literature; came to America as an emigrant, 1879, for the purpose of studying emigrant life; married in California, and resided after 1889 in Samoa. Among his works are, *An Inland Voyage* (1878); *Travels with a Donkey* (1879); *Familiar Studies of Men and Books* (1882); *Treasure Island* (1883); *A Child's Garden of Verses* (1885); *The Strange Case of Dr. Jekyll and Mr. Hyde* (1886); *The Silverado Squatters* (1883); *Memoirs and Portraits* (1887); *The Master of Ballantrae* (1890); *Eight Years of Trouble in Samoa* (1892); *David Balfour* (1893); *Island Nights' Entertainments* (1893); *The Ebb Tide* (1894). He died in December, 1894.

STEVENS POINT, city and co. seat of Portage co., Wis.; on the Wisconsin river and the Green Bay and Western and the Wisconsin Central railroads; 63 miles w. of Appleton. It is an important lumbering center, particularly for pine; has good waterpower; and contains the shops of the Wisconsin Central railroad, a large number of saw, planing, and shingle mills, foundries and flour mills. There are gas and electric light plants, national and state banks, and daily and weekly newspapers. Pop. '90, 7896.

STEWARD OF ENGLAND, LORD HIGH, one of the great officers of state, and anciently the first officer of the crown in England. The dignity was in early times hereditary. From Hugh Grentmesnell, lord steward in the time of Henry II., it passed by the marriage of his daughter and co-heir to the family of De Bellomonts, earls of Leicester, and thence also by marriage to the Montforts, earls of Leicester. On the death and attainder of Simon de Montfort, earl of Leicester, in 1265, the office, reverting to the crown, was granted with the earldom of Leicester to Edmund, younger son of Henry III., and continued annexed to the earldoms of Lancaster and Leicester, till absorbed into the royal dignity on the accession of Henry IV. Since that time, there has been no permanent lord steward, but the office is temporarily revived when occasion requires, a lord steward being appointed under the great seal *pro hac vice* at a coronation, or the trial of a peer (see PARLIAMENT). When the proceedings are at an end, the lord steward terminates his commission by breaking his wand of office.

STEWARD OF THE HOUSEHOLD, LORD, an officer of the royal household in England, of great antiquity, originally designated the lord great master of the household. He is the head of the ancient court called the *board of green cloth*, and as such has the control of all the officers and servants of the household, except those belonging to the chapel, the chamber, and the stable. The other members of the board of green cloth are the treasurer and the controller, over whom, as well as the master of the household, the lord steward's authority extends. That court had, by 3 Hen. VII. c. 14, and 33 Hen. VIII. c. 12, authority to try and punish all treasons, misprisions, murders, manslaughter

ters, bloodsheds, etc., in the royal palace, and within the verge of the court. But this jurisdiction, which had long fallen into disuse, was in part repealed by 9 Geo. IV. c. 31, and altogether abolished by 12 and 13 Vict. c. 101; and the functions of the board of green cloth are now confined to the supervision of the household expenses and accounts, the purveyance of the provisions and their payment, and the good government of the servants of the household. The lord steward selects all the subordinate officers and servants, except those connected with the royal stables; he also appoints the queen's tradesmen. He is always sworn a member of the privy council, and has precedence of all peers of his own degree. He has no formal grant of office, but receives his charge from the sovereign in person, who, delivering to him a white wand as his staff of office, says: "*Seneschal, tenez le bâton de notre maison.*" He holds his appointment during pleasure, and his tenure depends upon the political party to which he belongs. The salary of the office is £2,000.

STEWART, a co. in w. Georgia, having the Chattahoochee river for its w. boundary, separating it from Alabama; 450 sq.m.; pop. '90, 15,682. It is drained by the Han-nabatchee and Pataula creeks. Co. seat, Lumpkin.

STEWART, a co. in n.w. Tennessee, adjoining Kentucky; drained by the Cumberland and Tennessee rivers, the latter of which bounds it on the w.; crossed by the Louisville and Nashville railroad, about 500 sq.m.; pop. '90, 12,193, inclu. colored. The surface is rolling. The soil is fertile. The principal productions are corn, cotton, and tobacco. Co. seat, Dover.

STEWART, THE FAMILY OF. The origin of the Stewarts, long obscured by myth, was rediscovered in the beginning of the present century by the indefatigable antiquary, George Chalmers. Alan, son of Flahald, a Norman, accompanied the conqueror into England, and obtained by his gift the lands and castle of Oswestry in Shropshire. His eldest son, William, remaining in England, became the ancestor of the Fitzalans, earls of Arundel, from whom the duke of Norfolk inherits that earldom through an heiress. The second son, Walter, passing into Scotland in the service of David I., had large territorial possessions conferred on him by that monarch, along with the dignity of steward of Scotland, which became hereditary in his family, and was assumed by his descendants as a surname; some branches of the house, when spelling began to be considered, modifying the orthography to Steuart, or the French form Stuart. The fess chequy adopted as the arms of the family is emblematical of the chequer of the steward's board. The connection between the Stewarts and Fitzalans was shown by Mr. Chalmers to have been well known and acknowledged as late as 1336, when Richard Fitzalan, earl of Arundel, sold the stewardship of Scotland to his sovereign, Edward III. and Edward Balliol, as king of Scotland, ratified the transaction; the sale being a political fiction, founded on a supposed forfeiture of the Scottish branch of the family, by which the hereditary office reverted to the English branch.

The lands conferred on Walter the steward by David I. included the barony, or what is now the county of Renfrew, which became the chief patrimony of the family, as well as Innerwick, Hassendean, and other large estates in Teviotdale and Lauderdale. For seven generations the stewardship continued to descend without a break from father to son. Walter, the third, and grandson of the first steward, held, in addition, the office of justiciary of Scotland, and was one of the two ambassadors sent to conduct Marie de Couci, second wife of king Alexander II., to her adopted country. His third son, Walter, called Balloch, by his marriage with the younger daughter of Maurice, earl of Menteith—the lady's elder sister having been banished and her rights forfeited—got the earldom of Menteith, and was ancestor of a line of earls and countesses of Menteith, of whom the countess Margaret carried the earldom to her husband, Robert, duke of Albany, son of king Robert II. Alexander, fourth steward, was regent of Scotland in Alexander III.'s minority; he commanded at the battle of Largs in 1263, when the Scotch army obtained a signal victory over Haco of Norway; and invading the isle of Man, annexed it to the Scottish crown. From his second son, sir John Stewart, who married the heiress of Bonkyl, sprang various important branches of the family, including the Stewarts of Darnley, Lennox, and Aubigné. James, the fifth steward, was one of the six regents of Scotland after the death of Alexander III. Walter, the sixth steward, occupies a conspicuous place among Bruce's companions-in-arms. When but a youth, he did considerable service as one of the principal leaders at Bannockburn, and, four years later, increased the promise of his fame by his successful defense of Berwick against Edward II. in person. His marriage with Marjory, daughter of Robert Bruce, eventually brought the crown of Scotland to his family. He died at the age of 33, much lamented throughout Scotland. His son by Marjory Bruce, Robert, seventh high steward, was regent from 1338–41, and afterward during the captivity of his uncle, David II., from 1346–57; and in the midst of events which threatened a total overthrow to the liberties of Scotland, he exerted himself with zeal and energy in their defense, and was the main instrument in defeating the intrigues of David II. and Edward III. to place an English prince on the throne. On the death of David II. in 1371 he ascended the throne as Robert II., and died in 1390. He was twice married; first to Elizabeth, daughter of sir

William Mure of Rowallan, and afterward to Euphemia, countess of Moray, daughter of Hugh, earl of Ross, and had issue by both unions. In consequence of Elizabeth Mure being related to him within the prohibited degrees, he obtained a dispensation for the marriage from pope Clement VI. in 1347, in which those children who had already been born, as well as those to be born of that connection, were legitimated; and the succession to the crown was further regulated by parliament. In later times, when the true history of these proceedings was lost or mystified, the descendants of Robert II.'s first marriage came to be branded with the suspicion of illegitimacy, while those of the second marriage were in the habit of boasting of their preferable claim to the throne; and the dispensation setting the question at rest was only discovered in the Vatican in 1789 by Andrew Stuart of Castlemilk. Of the children by the first marriage, the third son, Robert, duke of Albany, and his issue are separately noticed below. The fourth son, sir Alexander Stewart, who got the earldom of Buchan on the forfeiture of the Comyns, ruled over the northern part of Scotland with little less than regal authority, and his savage and ferocious character obtained for him the appellation of the "Wolf of Badenoch." He had no lawful issue, but several natural sons, one of whom stormed the castle of Kildrummy, the residence of the countess of Mar, forcibly wedded that lady, and possessed himself of the earldom; and others were progenitors of the branches of the family known as the Athole Stewarts, of whom the principal were the Stewarts of Garth. For the subsequent history of the royal family, see articles ROBERT II. and III.; JAMES I., II., III., IV., V.; MARY, QUEEN OF SCOTS; JAMES I. (of England); CHARLES I. and II.; JAMES II.; WILLIAM III.; and ANNE.

James II. (of England) was twice married, first to lady Anne Hyde, daughter of lord-chancellor Hyde; and secondly, to Mary Beatrice, daughter of the duke of Modena. By the first marriage he had Mary, queen of William III., and Anne, who succeeded to the throne, neither of whom left issue; and by the second, James, prince of Wales, born in 1688, known as the chevalier St. George, or the elder pretender. Prince James, who was born but a few months before his father's abdication, was commonly but groundlessly alleged to be a supposititious child, and was involved in his father's exclusion from the crown. In 1715 the party who supported him, known in history as the Jacobites, endeavored to procure him the throne by force of arms. In Scotland, the earl of Mar, with about 5,000 men, engaged the royal forces under the duke of Argyll at Sheriffmuir: it was a drawn battle, but the result was a delay as fatal as a defeat. In England, the rising was headed by the earl of Derwentwater, and ended by the unconditional surrender of the insurgents at Preston, when lords Derwentwater and Kenmore were beheaded, and other persons of note executed and attained. James escaped to France; and for the rest of his life resided in obscurity principally at Rome, where he died in 1766. In 1719 he married one of the wealthiest heiresses in Europe, Maria Clementina Sobieski, granddaughter of John Sobieski, king of Poland, and by her had two sons, Charles Edward Lewis Casimir, born 1720, known as the young pretender (see STUART, CHARLES EDWARD), and Henry Benedict Maria Clement, cardinal York, born 1725. Henry Benedict, second son of the chevalier St. George, went to France in 1745 to head an army assembled at Dunkirk for the invasion of England, but the news of the defeat of Culloden put an end to his plan. He then returned to Rome, took orders, and was advanced to the purple by Benedict XIV. in 1747. During his brother's life, he was known as cardinal York; but after his death he assumed the regal style as Henry IX., king of England. His various bishoprics and rich church livings enabled him for long to live in great splendor; but the expulsion of Pius VI. from Rome, and other events of the revolution, drove him to Venice, aged and infirm, stripped of his means, and reduced to absolute poverty. His deplorable situation becoming known to the British court, George III. settled on him an annuity of £4,000, which the cardinal accepted with gratitude, and enjoyed during the remainder of his life. He died in 1807 at the age of 82, the last surviving descendant of James II.

Next to the exiled Stewarts in representation of the royal house as heir-of-line came the descendants of Henrietta Maria, daughter of Charles I., who was married to Philippe, duke of Orleans, brother of Louis XIV. of France. This princess had two daughters, of whom the elder, Mary, was queen to Charles II. of Spain, but died childless; the younger, Anna Maria, married Victor-Amadeus, duke of Savoy and king of Sardinia, and was mother to Charles-Emmanuel III., king of Sardinia, and grandmother to Victor-Amadeus III., king of Sardinia. Victor-Amadeus had three sons who successively occupied the Sardinian throne as Charles-Emmanuel IV., Victor-Emmanuel I., and Charles-Felix, and a daughter who married Charles X. of France, and was mother of Henri, duc de Bordeaux, present representative of the French Bourbons. Victor-Emmanuel and Charles-Felix left daughters only; and the present senior co-representative as heir-of-line of the house of Stewart, as well as that of Tudor, is Maria Teresa, wife of prince Louis of Bavaria and only child of the younger brother of the last duke of Modena, grandson of Victor-Emmanuel IV. The house of Savoy-Carignan, from which the king of Italy springs, does not participate in the Stewart descent.

The branch of the family which the parliamentary settlement called to the throne on the death of Anne were the descendants of the electress Sophia of Hanover, granddaughter of James VI. by her mother the princess Elizabeth Stewart, electress palatine and queen of Bohemia. By this destination, not only were the already mentioned

descendants of Charles I.'s daughter, the duchess of Orleans, excluded, but also the sons of the king of Bohemia and their descendants. The eldest son, Charles Lewis, duke of Bavaria, is represented through his daughter, the duchess of Orleans, by the comte de Paris, grandson of Louis Philippe, late king of the French. Her majesty queen Victoria is sixth in descent from and representative of the electress Sophia, the line of descent being through George I.; George II.; Frederick, prince of Wales; George III.; and Edward, duke of Kent.

We have now briefly to notice the most important cadets of the house of Stewart.

DUKES OF ALBANY, EARLS OF MARCH, LORDS OF ANNANDALE AND MAN.—The dukedom of Albany, forfeited on the attainer of duke Murdoch, nephew of Robert III. (see *infra*), was conferred on Alexander, second son of king James II. of Scotland, who also obtained the earldom of March, and lordship of Annandale and Man. Albany, falling under suspicion of James III., was arrested, and escaping from custody in Edinburgh castle to France, was attainted. He afterward took part in a plot with the discontented barons and Edward IV. of England to place himself on the throne, and joining the English army, captured Berwick. After making his peace with James, and being restored to his dukedom, he again rebelled, and invading Scotland with the earl of Douglas, was routed at Lochmaben, and once more attainted. He was first married to lady Catherine Sinclair, daughter of the earl of Orkney and Caithness, from whom he obtained a divorce on the ground of propinquity of blood, by which his son Alexander was bastardized. By his second wife, the daughter of Bertrand, count de la Tour d'Auvergne, he had a son John, who was restored to the dukedom, assumed the regency of Scotland in James V.'s minority, and was declared heir to the throne. By the settlement of the crown under Robert II., John, duke of Albany, would, had he survived James V., have had a preferable claim to Mary. After a regency of eight years, during which he gave offense by his hauteur and French predilections, he returned to France, became governor of Bourbonnais, attended Francis I. in his unfortunate expedition into Italy in 1525, and died in 1536. By his wife, Anne de la Tour d'Auvergne, he left no issue.

DUKES OF ALBANY, EARLS OF FIFE AND MENTEITH.—Robert, second surviving son of Robert II. and Elizabeth Mure, obtained the earldom of Menteith by marriage with its heiress, and the earldom of Fife by indenture with his sister-in-law, the countess, and was appointed great chamberlain of Scotland in 1383. He practically exercised the regency during his father's declining years, and continued to wield the supreme authority after the succession of his timid and irresolute brother, Robert III., who bestowed on him the title of duke of Albany—i.e., of all Scotland north of Forth and Clyde. His unscrupulous ambition led him to get rid of his nephew, the duke of Rothesay, by starving him, in order to pave his way to the throne; and prince James was sent abroad by his father, lest he should meet a similar fate. On Robert III.'s death, Albany at once became regent of Scotland, and wielded the chief power of the state during the minority and captivity of James I. By his first marriage to Margaret, countess of Menteith, he had a son, Murdoch, who, on his father's decease in 1419, succeeded, unchallenged, to the regency. By his second wife, Muriella, daughter of sir William Keith, the marischal, he had, besides two younger sons of whom there was no succession, a son, John, created earl of Buchan, on whom Charles VII. bestowed the office of constable of France after the battle of Baugé, and who fell at Verneuil, leaving only a daughter, who married the second lord Seton, and is represented by the earl of Eglinton. Duke Murdoch married the eldest co-heiress of the earl of Lennox, and had four sons. On James I.'s restoration, his vengeance fell on duke Murdoch, his sons Walter and Alexander, and his father-in-law Lennox, who were all put to death, and the dukedom of Albany forfeited to the crown. Murdoch's youngest son, James, generally known as "James the Gross," escaped to Ireland, where he had a numerous issue by a lady of the family of the lords of the Isles, some of whom were brought to Scotland, and raised to high honors by James II., and received letters of legitimization, which in the 15th c. conferred far more nearly than at a later date the full rights of legitimacy. The eldest, who was created Lord Avandale, enjoyed for life the estates of the earldom of Lennox, which had belonged to his grandmother, to the exclusion of the descendants of that lady's sisters; and we afterward find the earl of Arran, a descendant of the sixth son of James the Gross, entering a protest in the parliament of 1585 regarding the perfect legitimacy of the house of Ochiltree. From the youngest son, James (not legitimated), sprung the Stuarts of Ardvorlich, Glenbuckie, and others in Balquidder.

LORDS AVANDALE, OCHILTREE, AND CASTLESTUART; EARLS OF CASTLESTUART.—Andrew Stewart, eldest legitimated son of James the Gross, and grandson of Murdoch duke of Albany, was created lord Avandale in 1455, and held the office of chancellor to James III. On his death without issue in 1488, he was succeeded by his nephew, Andrew, eldest son of his also legitimated brother, Walter, who had three sons. The eldest of these, Andrew, third lord Avandale, exchanged his title for that of Ochiltree, and was father of Andrew, second lord Ochiltree, sometimes called the "good lord Ochiltree," an active promoter of the reformed faith, one of the lords of the congregation, and an accomplice in the assassination of Riccio. One of his daughters became the second wife of John Knox; and his younger son, James, has an unenviable notoriety in history. He was the unprincipled and arrogant favorite of James VI.'s early

years; held, along with other offices, that of chancellor of Scotland; was created earl of Arran on the forfeiture of the Hamilton family; and enriched himself with the spoils of the estates of Angus, Mar, Glamis, and other forfeited lords. But his downfall was as sudden as his elevation. At the raid of Stirling, in 1585, he was stripped of his honors, offices, and spoils, the earldom of Arran being restored to the Hamiltons; and in 1596 he was assassinated by sir James Douglas. The second lord Ochiltree was succeeded by his grandson, Andrew, third lord Ochiltree, who resigned the lordship of Ochiltree to his cousin, sir James Stewart of Killeith, son of the earl of Arran, settled in Ireland, where extensive lands were bestowed on him by James VI., and was in 1619 created lord Stuart of Castlestuart in the peerage of Ireland. After the death of the fifth lord Castlestuart in 1684, the title remained dormant till claimed by Andrew, ninth lord, as heir-male of the body of the first lord, which claim was proved to the satisfaction of the Irish house of lords in 1774. The younger branch of the house, to whom the title of Ochiltree was transferred, had come to an end in 1673, and lord Castlestuart claimed also the Ochiltree title; but the evidence adduced by him was held insufficient by the British house of lords. He was, in 1793, created viscount Castlestuart, and, in 1800, earl of Castlestuart; and the present and fifth earl is his great-grandson.

LORDS METHVEN.—Henry Stewart, second son of Andrew, second lord Avandale, became, in 1526, third husband of the princess Margaret of England, widow of James IV., and divorced wife of Archibald, earl of Angus. In 1528 he was created lord Methven. He left no children by the queen-dowager, but by a second marriage had a son, who became second lord Methven, and in the person of whose son, the third lord, the succession terminated.

LORDS DOUNE, EARLS OF MORAY, LORDS ST. COLME.—Sir James Stewart of Beath, third son of Andrew, second lord Avandale, obtained from James V. the hereditary command of the castle of Doune, with the stewardry of Menteith. He had two sons, from the younger of whom sprang the Stewarts of Burray in Orkney. The elder son, James, on the dissolution of the monasteries, obtained the lands of St. Colme, and was created lord Doune in 1581. His son, the second lord Doune, married Elizabeth, the only child of James Stuart, earl of Moray, regent of Scotland, natural son of James V. by Margaret, daughter of John, lord Erskine (see MURRAY, JAMES, EARL OF) and, thereupon became earl of Moray. This nobleman is known in history as the "bonny earl of Moray," and fell a victim to his hereditary enemy, the earl of Huntly, in 1592. His son, the third earl, is believed to have got a new investiture to heirs-male, and from him descends the present and fourteenth earl of Moray. The ninth earl became, in 1796, a peer of Great Britain, as baron Stuart of Castlestuart. Henry Stuart, younger brother of the "bonny earl of Moray," was made a lord of parliament as lord St. Colme in 1611, a title which, however, became extinct on his son's death without issue, and the estates reverted to the earl of Moray. The family of Stuart of Dunearn sprang from a younger brother of the fifth earl.

EARLS AND MARQUISES OF BUTE, LORDS WHARNCLIFFE, LORDS STUART DE ROTHESAY.—Sir John Stuart, a natural son of Robert II., was made hereditary sheriff of Bute and Arran; and his descendant and representative, sir James Stuart, had a baronetcy conferred on him in 1627. Sir James Stuart, grandson of the above sir James, a privy councillor to queen Anne, and a strenuous opponent of the union, was raised to the peerage as earl of Bute. The fourth earl was advanced to the marquise of Bute. The present peer is the third marquis. Two grandsons of the third earl were raised to the peerage as lord Wharncliffe, and a grandson of the same earl, lord Stuart de Rothsay (the latter title is now extinct); and a grandson of the first marquis as lord Stuart de Decies.

EARLS OF ANGUS.—Sir John Stewart (commonly called of Bonkyl), brother of James, fifth steward of Scotland, was progenitor of some of the most considerable branches of the family, and direct ancestor in the male line of James VI. and the Stuart kings who followed him. He married Margaret, daughter and heiress of sir John Bonkyl of Bonkyl, in virtue of which alliance most of his descendants added the bend or buckle of the Bonkyl coat to the fess of the Stuart escutcheon. The issue of this marriage was five sons—1. Sir Alexander Stewart of Bonkyl; 2. Sir Alan Stewart, of Dreghorn; 3. Sir Walter Stewart of Dalswinton; 4. Sir John Stewart of Jedworth; 5. Sir James Stewart of Pierston; and a daughter, Isabel, who married the celebrated Thomas Randolph, earl of Moray, nephew of Robert Bruce. The eldest son, sir Alexander, succeeded to Bonkyl on his maternal grandfather's death, and was father of sir John Stewart, created earl of Angus in 1329. The third earl, grandson of this sir John, was the last male descendant of sir Alexander of Bonkyl; and on his death the earldom devolved on his sister, Margaret Stewart, countess of Angus in her own right. This lady was married to Thomas, earl of Mar, by whom she had no issue; but she had a natural son, George, by William, first earl of Douglas (a connection then deemed incestuous, the earl being brother-in-law to her husband), upon whom, on her resignation, the earldom of Angus was conferred by Robert II. in 1389, and who was ancestor of the Douglasses, earls of Angus.

EARLS OF DARNLEY, EARLS AND DUKES OF LENNOX, LORDS OF AUBIGNÉ.—Sir Alan Stewart of Dreghorn, second son of sir John of Bonkyl, who with his brothers, John and James, fell at Halidon hill in 1333, was ancestor of this distinguished line.

His domains included the extensive lands of Cruickston and Darnley, in Renfrewshire, to which his grandson, sir Alexander Stewart, added Galston by his marriage with Janet, daughter and heiress of sir William Keith of Galston, and widow of sir David Hamilton of Cadyow. Sir John Stewart of Darnley, eldest son of this marriage, distinguished himself much in the French wars, when succors were sent from Scotland to the aid of the dauphin, afterward Charles VII. He was constable of the Scots army in France, and contributed greatly to the victory of Baugé, in recompense for which the lands and lordship of Aubigné and Concessault, in France, were conferred on him, as well as the county of Evreux, with permission for himself and his descendants to quarter the royal arms of France. In 1428, he was one of the ambassadors sent by Charles to negotiate a marriage between the dauphin and the princess Margaret of Scotland; and in the following year, along with a younger brother, William, fell at the siege of Orleans. His marriage with Elizabeth, one of the daughters and co-heirs of Duncan, earl of Lennox, afterward added the Lennox estate to the family possessions. According to arrangements made by permission of the king of France, the lordship of Aubigné was generally enjoyed by a younger member of the family; it went in succession to the third son of sir John Stuart, and to his son, Bernard Stuart. The latter, alike distinguished for military and statesmanlike qualities, had a share in the victory of Bosworth, and supported by arms Charles VIII.'s claim to the throne of Naples. He held, among other dignities, those of viceroy of Naples, constable of Sicily and Jerusalem, and duke of Terra Nova. His grandson, sir John Stuart, was advanced to the dignity of a lord of parliament under the title of lord Darnley; he was also served heir to half the Lennox domains, and claimed the earldom of Lennox. His elder son, Matthew, second earl of Lennox, fell at Flodden; his younger son, Robert, got the lordship of Aubigné in 1508, on the death, without issue, of Bernard Stuart, whose daughter was his first wife, John, the third earl of Lennox, was son of the second earl by Elizabeth, daughter of James, lord Hamilton, and niece of James III.; he was one of the lords of the regency in James V.'s minority, and in endeavoring to rescue the youthful king from the thralldom of the Douglasses, he was taken prisoner at Linlithgow, and murdered by sir James Hamilton of Finnart, Arran's natural son. This earl was married to lady Anne Stewart, daughter of John, earl of Athole, and had three sons, Matthew—who succeeded him as fourth earl—Robert, and John. The termination of the male line of Robert III. by the death of James V., along with the imperfect legitimacy of the descendants of the house of Albany, placed Matthew, earl of Lennox, in the position of heir-male of the stewards of Scotland. He married lady Margaret Douglas, only child of Archibald, earl of Angus, by the queen-dowager Margaret, sister of Henry VIII., an alliance which brought his children into the position of being nearest heirs after Mary, queen of Scots, to the crown of England. The issue were two sons, the elder of them the unhappy husband of the unhappy queen Mary, and father of James VI. Lennox, after spending his youth in France and in the wars in Italy, returned home in 1543, and took an active part in the negotiations for the proposed marriage of queen Mary with Edward VI. His subsequent intrigues with England led to his banishment and attainder, but he was recalled and restored to his honors by Mary. After that queen's forced resignation, he was appointed to the regency, and when on his way to hold a parliament at Stirling in 1571, he was attacked by a party of the queen's friends and mortally wounded.

The earldom and estates of Lennox, which, on the death of the fourth earl, had devolved on James VI. by right of blood, were conveyed by him to his uncle, Charles, fifth earl of Lennox, brother of lord Darnley. The marriage of this earl in 1574, with a sister of the first earl of Devonshire, gave great displeasure to Elizabeth, whose own doubtful legitimacy made her very sensitive to possible pretensions to the throne. The sole issue of that union was a daughter, Arabella, and the earldom went in succession to the fifth earl's uncle, Robert, bishop of Caithness, and his cousin, Esme, son of John Stewart, lord of Aubigné, youngest son of the third earl of Lennox, who was created duke of Lennox. The near relationship to the crown, both of England and Scotland, in which the fifth earl's daughter, the unfortunate lady Arabella Stewart, stood, made her an object of jealousy equally to James and Elizabeth. Elizabeth first interfered to prevent her contemplated marriage with her cousin, Esme, duke of Lennox, and afterward imprisoned her for listening to overtures from a son of the earl of Northumberland. The result was, that this lady formed an illicit connection with William Seymour, afterward marquis of Hertford; on the discovery of which, both were summoned by James before the privy council, and severely reprimanded. The consequence was the reverse of what was intended. Lady Arabella privately married Seymour; which becoming known, she and her husband were committed into custody. Both effected their escape: lady Arabella was overtaken in Calais roads, and imprisoned in the tower, where these undeserved oppressions drove her to a condition of lunacy, in which she died, Sept. 27, 1615. Esme, first duke of Lennox, had two sons, Ludovio and Esme, successively second and third dukes of Lennox. The former held the offices of great chamberlain and high admiral of Scotland, and was created earl of Richmond, earl of Newcastle, and duke of Richmond in the peerage of England. The latter, who was also lord of Aubigné, was created earl of March in England, and was father of James, fourth duke of Lennox, who fell under the guardianship of James VI. as his nearest heir-male, and had the title of duke of Richmond, which had expired at his uncle's

death, revived in his favor in 1641. On the death of the sixth and last duke without issue in 1672, king Charles II., as nearest heir-male, was served heir to him in special.

LORD PITTENWEEM.—Alexander Stewart of Galston, younger brother of the first lord Darnley, got from his brother the lands of Dregghorn and Galston. His great-grandson, Thomas Stewart of Galston, had two sons, Thomas and William. The younger son, William, became commendator of the priory of Pittenweem, and his son was made a lord of parliament as lord Pittenweem. The line of the elder son, Thomas, failed in 1650 in the person of Ludovic Stuart of Galston.

STUARTS OF CASTLEMILK.—The earliest proved ancestor of this important and well-allied branch of the Stewarts, was sir William Stewart of Castlemilk, who in 1398 was appointed umpire for the preservation of the western marches, probably descended from the Stewarts of Darnley. Archibald Stuart of Castlemilk was created a baronet of Nova Scotia by Charles II. His line failed on the death of sir John Stuart, fifth baronet, in 1797, when the succession devolved on Andrew Stuart of Torrance and Castlemilk, M.P., the author of *The Genealogical History of the Stewarts*, descended from an uncle of the first baronet, who died without issue.

STEUARTS OF ALLANTON, COLTNESS, etc.—This family, which first came into notice in the 16th c., and includes various men of eminence who would do honor to any line of ancestry, is of unascertained descent, but some traditional accounts make it a branch of Castlemilk. Sir James Steuart of Coltness and Kirkfield, younger brother of sir Walter of Allanton, and his son, sir Thomas, were active Covenanters; and the latter, an energetic member of king William's first parliament, and the framer of the act of 1690 for the regulation of the church of Scotland, was in 1698 made a baronet. His son, sir David Steuart of Coltness, accompanied Archibald, earl of Argyll, in his descent on Scotland, for which he was sentenced to death, but escaped, and was afterward pardoned. His brother, sir Robert Steuart, fourth baronet, was among the more distinguished scientific men of the beginning of the 18th c., and filled the natural philosophy chair in the university of Edinburgh, in which he was succeeded by his son. Sir James Steuart of Goodtrees, lord advocate under king William and queen Anne, author of the *Answers to Dirleton's Doubts*, and one of the most eminent jurists of his time, was younger brother to the first baronet of Coltness. His son, sir James Steuart of Goodtrees and Coltness, also a distinguished lawyer, and created a baronet in 1705, was father of another sir James, who was prince Charles's confidential agent at the court of France, and at the same time the author of various works of merit on political economy and kindred subjects.

EARLS OF GALLOWAY.—Sir Walter Stewart of Dalswinton, third son of sir John of Bonkyl, obtained the lands of Dalswinton from king Robert Bruce, and Garlies from his nephew, John Randolph, earl of Moray. His grandson, sir Walter of Dalswinton, left an only daughter, Marion, who married sir John Stewart, son of sir William Stewart of Jedworth, and probably a descendant of John, fourth son of sir John of Bonkyl. Sir Alexander Stewart of Garlies, eighth in descent from sir John and Marion Stewart, was created lord Garlies in 1607, and earl of Galloway in 1623. In 1796, John, seventh earl of Galloway, was created a British peer as baron Stewart of Garlies. Alan Plantagenet Stewart, tenth earl of Galloway, is present representative.

LORD BLANTYRE.—This branch of the house of Stewart is descended from sir Thomas Stewart of Minto, third son of sir William of Dalswinton and Garlies, the eldest son of the heiress, Marion Stewart. Sir John Stewart of Minto, great-grandson of that sir Thomas, had two sons. The line of the elder, sir Matthew, became extinct in the person of sir John Stuart, who died in the Darien expedition of 1697. The second son, Walter, was educated along with James VI. under George Buchanan, and had the priory of Blantyre bestowed on him by that monarch: he was privy councillor, keeper of the privy seal, one of the four commissioners of the treasury and exchequer, called octavians, and afterward high treasurer. In 1606 he was raised to the peerage as lord Blantyre. The present representative of this branch is Charles Stuart, twelfth lord Blantyre.

VISCOUNTS MOUNTJOY, EARL OF BLESSINGTON.—Sir William Stewart, descended from Walter Stewart of Tonderghie, fourth son of sir William of Dalswinton and Garlies, who was in great favor with James VI., and undertaker for the plantation of escheated lands in Ulster, was made a baronet of Ireland in 1623. His grandson, sir William Stewart, second baronet, was in 1682 created baron Stewart of Ramalton, and viscount Mountjoy in the peerage of Ireland. He served in Hungary at the siege of Buda, and in 1688 undertook a mission from lord-deputy Tyrconnel to James II., then at Paris, when he was thrown into the Bastille, and was a prisoner there for four years. He afterward joined king William at Flanders, and was killed at the battle of Steinkirk. The second viscount, his son, married the daughter and eventually heiress of viscount Blessington. Their son, the third viscount Mountjoy, was advanced to the earldom of Blessington, which title, as well as that of Mountjoy, became extinct on his decease in 1769, though the baronetcy exists.

EARLS OF ATHOLE, LORDS OF LORN AND INNERMEATH.—Sir James Stewart, fifth son of sir John of Bonkyl, killed with his brothers Alexander and John at Halidon hill, had a grant from Robert Bruce of the lands of Pierston and others in Ayrshire, and was father of sir Robert Stewart of Shanbothy and Innermeath. This sir Robert had two sons, John and Robert, who married the two co-heiresses of the princely house of De

Ergadia, lord of Lorn, who were also co-heirs of the line of Robert Bruce. The younger son, Robert of Durrisdere, was ancestor of a line of Stewarts of Rossyth and Craigiehall, to whom Oliver Cromwell's mother is said, on no very certain grounds, to have belonged, and which probably came to an end about 1830. The elder son, sir John, whose wife was the elder and principal co-heiress, had five sons. The eldest, Robert, became lord of Lorn; the third, sir James, known as the black knight of Lorn, was husband of James I.'s widow; and his eldest son, brother uterine of James II., was created earl of Athole, with remainder to the heirs-male of his body. His great-grandson, John Stewart, fourth earl of Athole, was much involved in the political events of Mary's and James VI.'s time. An adherent of the old faith, and at first a staunch supporter of the queen, he nevertheless assisted in her seizure, and took a lead in the association formed in 1567 for the defense of James VI. He headed the confederacy which took up arms against the regent Morton, and induced James to call a parliament. In 1577 he became chancellor of Scotland, and died suddenly under suspicion of poison from Morton. His son, the fifth earl of Athole, had no male issue, but daughters, of whom the eldest was married to the earl of Tullibardine; and at his death, the earldom fell to the crown, and was conferred on the elder branch of the house of Innermeath, to which we now revert.

Robert, lord of Lorn, eldest brother of the black knight, had two sons. The elder of these, John, second lord of Lorn, had three daughters, co-heiresses, who respectively married the earl of Argyll, Campbell of Glenorchy, and Campbell of Ottar, the lordship of Lorn passing to the Argyll family; he had also a natural son, ancestor of the Stewarts of Appin. The second son of Robert, lord of Lorn, was Walter, lord Innermeath, whose descendant and representative, John, sixth lord Innermeath, obtained the earldom of Athole on the death of the above-mentioned fifth earl; with a remainder to the heirs-male of his body, which came to an end on the death, in 1625, of his only son, who had succeeded him in the earldom. The earldom of Athole was then conferred by Charles I. on the earl of Tullibardine, grandson through his mother of the fifth earl of Athole, from whom the existing ducal house of Athole is descended. From Alexander, fourth son of sir John Stuart of Innermeath, descend the family of Stewart of Grandtully, on whom a baronetcy was conferred in 1683.

EARLS OF BUCHAN.—The earldom of Buchan was, in 1469, bestowed on James Stewart, second son of the black knight of Lorn, and brother uterine of James II. By his marriage with the heiress of Auchterhouse, his family became heritable sheriffs of the county of Forfar. His legitimate line ended in the fourth generation in an heiress, Christian, countess of Buchan, who, marrying a son of sir Robert Douglas of Lochleven, carried the earldom of Buchan into his family.

EARLS OF TRAQUAIR.—This James Stewart, first earl of Buchan, had, besides his lawful issue, a natural son, James, legitimated in 1489, on whom his father conferred the lands of Traquair. His descendant, sir John Stuart, was created by Charles I. lord Stuart of Traquair in 1628, and, in 1633, earl of Traquair. The title became extinct or dormant on the death of the eighth earl in 1861.

Various works have been written to elucidate the history of the Stewart family, or particular branches of it, including Symson's *General and Historical Account of the Stewarts* (Edin. 1712); Hay of Drumboote's *Essay on the Origin of the Royal Family of the Stewarts* (1722); Duncan Stewart's *Historical and Genealogical Account of the Royal Family of Scotland, and of the Surname of Stewart* (Edin. 1739); Noble's *Historical Genealogy of the Royal House of Stewart* (Lond. 1795); and Andrew Stuart of Castlemilk's *Genealogical History of the Stewarts* (Lond. 1798), a work full of laborious research, but nearly confined to the houses of Darnley, Lennox, and Castlemilk. See also *The Genealogy of the Stewarts Refuted* (Edin. 1799), and the rejoinder to it in Andrew Stuart's *Supplement to the Genealogical History of the Stewarts* (1799); Chalmers's *Caledonia* (1807—24); Crawford's *Description of the Shire of Renfrew, with Supplement* by George Robertson (Paisley, 1818); Fraser's *Red Book of Grandtully* (Edinburgh, 1868).

STEWART, ALEXANDER, LL.D., 1781—1862; b. Scotland; was minister of Douglas. He published *Cornelius Nepos* with notes; *Mair's Introduction*; *Goldsmith's England*, with continuation; *History of Scotland*; *Stories from the History of Scotland*; *Discourses*; *Compendium of Modern Geography*. He was one of the leading contributors to the *Edinburgh Encyclopædia*.

STEWART, ALEXANDER TURNEY. 1803—76; b. Ireland; educated at Belfast, and at Trinity college, Dublin; came to New York about 1823, and was usher in a private school, but in 1825 engaged in the dry-goods business. In 1841 he married Miss Cornelia M. Clinch; and in 1848—49 erected the magnificent store corner of Broadway and Chambers street, having purchased the property for \$62,000. His business, which was already enormous, continued to extend until it dwarfed all others in the same line in the country; and in 1862 Mr. Stewart found it necessary to follow the tendency toward the upper part of the island, and erected the building corner of Broadway and Tenth street, at a cost of \$2,750,000. To this structure he removed his retail business, confining the lower store to wholesale transactions. In the mean time Mr. Stewart's business comprised agencies in Glasgow, Manchester, Belfast, Paris, Berlin, and Lyons; and mills in the United States at Holyoke, Mass.; New Hartford, N. Y.; Catskill, N. Y..

and in New Jersey. At the time of Mr. Stewart's death, April 10, 1876, his transactions were estimated to exceed \$65,000,000 per annum. He also owned much real estate, including Garden City, L. I., a settlement on Hempstead plains, which has grown to a considerable town; the Metropolitan Hotel and Niblo's Garden, the Globe Theatre; the Park Avenue (formerly the Women's) Hotel, cor. 32d street; and many other buildings and lots in New York; the Grand Union Hotel, Saratoga, etc. Mr. Stewart's residence, corner of Fifth avenue and Thirty-fourth street, contained perhaps the finest private gallery of paintings in the country. Mr. Stewart gave considerable sums in charity during his life-time, including aid to the Irish during the famine of 1847; a ship-load of flour sent to Havre, after the Franco-German war; \$50,000 to Chicago on the occasion of the great fire in 1871; \$100,000 to the U. S. sanitary commission during the war; \$10,000 to the Lancashire, England, operatives who were sufferers by the deficiency of American cotton during the same period; and the Women's Lodging-house in Park avenue; designed by him to be a hotel for young working-women, at low prices, but diverted after his death to the ordinary business of a public hotel, with ordinary rates. Mr. Stewart was buried in the family vault in St. Mark's church-yard, April 13, 1876. The grave was afterward robbed of its contents for the purpose of obtaining a ransom, but it is generally believed that the body was restored to the family, and lies in the mausoleum at Garden City (q.v.). Mr. Stewart bequeathed the sum of \$1,000,000 to ex-judge Henry Hilton, his confidential law adviser; who, with that sum, purchased from the widow her interest in the dry-goods business of A. T. Stewart and Co., which has since been discontinued. Mr. S. ('69) was nominated to the position of secretary of the treasury by President Grant, but the existence of an old law against an importer holding that position prevented his confirmation.

STEWART, BALFOUR, LL.D., b. Edinburgh, 1828; educated at St. Andrew's and Edinburgh. He became director of the Kew observatory, 1859, and professor of natural philosophy in Owens college, Manchester, in 1870. He has published an *Elementary Treatise on Heat; Lessons in Elementary Physics* (1871); *Physics* (1872); and *The Conservation of Energy* (1873). He discovered the law of equality between the radiative and absorptive powers of bodies. With Prof. Tait, he wrote *The Unseen Universe*. D. 1887.

STEWART, CHARLES, 1778-1869; b. Philadelphia; became a lieutenant in the U. S. navy in 1798. In 1800, in command of the schooner *Experiment*, he captured the French privateer *Deux Amis*, and the *Diana*. In 1804, in command of the *Siren*, he went with the American squadron against Tripoli. He was made capt. in 1806, and in 1813, on the frigate *Constitution* captured several British vessels. In 1815, after a fight lasting 1 hour and 40 minutes, he captured the British ships, *Cyane*, 34 guns, and the *Levant*, 21 guns; but the latter was recaptured. He was in command of the Mediterranean squadron, 1816-20, and the Pacific squadron, 1821-23. He became rear-admiral on the retired list in 1862.

STEWART, CHARLES SAMUEL, b. N. Y. 1795; graduated at Princeton college, 1815; studied law at Litchfield, Conn., and theology at Princeton; ordained a missionary to the Sandwich islands, 1822; visited the United States, 1826; appointed chaplain in U. S. navy, 1828; was chaplain of naval station New York, 1836-37. He published *Private Journal of a Voyage to the Pacific Ocean and Residence at the Sandwich Islands, 1823-25; Visit to the South Seas in U. S. Ship Vincennes, 1829-30; Sketches of Society in Great Britain and Ireland*. He d. 1870.

STEWART, DUGALD. This philosopher was b. in Edinburgh, on Nov. 22, 1753. His father was Matthew Stewart, professor of mathematics in the university of Edinburgh. He entered the high school in his eighth year, and remained till his thirteenth. During the last two years of his attendance, when in the rector's classes, he was principally under Alexander Adam, afterward well known for his classical scholarship, who then began to teach as the rector's substitute. His subsequent course at the university extended from 1765 to 1769. In the departments of study where his own career afterward lay, he was fortunate to find professors of ability and distinction; the logic chair was filled by John Stevenson, who lectured on logic, metaphysics, rhetoric, and the history of philosophy; the moral philosophy chair was occupied by Adam Ferguson. While Stewart gave his highest promise in these subjects, he also made great attainments in mathematics and natural philosophy, and likewise in classics. In 1771 he went to study at Glasgow, partly with a view to one of the Snell scholarships at Balliol college, Oxford, and partly to attend the lectures of Dr. Reid. It was while there that he wrote an essay on dreaming, which was his first effort in mental philosophy, and contained the germs of many of his subsequent speculations. He lived in the same house with Archibald Alison, the author of the *Essay on Taste*, and the two became intimate friends through life. He was at Glasgow only one session. In 1772, in his 19th year, he was called upon by his father, whose health was failing, to teach the mathematical classes in the university of Edinburgh; in 1775 he was elected joint professor, and acted in that capacity till 1785. In 1778 Adam Ferguson was absent from his post on a political mission to America, and Stewart taught the moral philosophy class in addition to his mathematical classes. The lectures that he gave on this occasion were wholly his own, and were delivered from notes, as was his practice in after years. On the resignation of

Ferguson in 1785 he was appointed professor of moral philosophy, and continued in the active duties of the class for 25 years. His lectures were greatly admired and numerous attended. He went over a wide compass of subjects: psychology, or the science of mind proper, metaphysics, logic, ethics, natural theology, the principles of taste, politics, and last of all, political economy, which, from the year 1800, he treated in a separate course. In 1792 appeared his first volume of the *Elements of the Philosophy of the Human Mind*. In 1793 he published his *Outlines*. He read before the Royal Society of Edinburgh, in 1793, his *Account of the Life and Writings of Adam Smith*; in 1796 the *Account of the Life and Writings of Principal Robertson*; and in 1802 the *Account of the Life and Writings of Dr. Reid*. In 1805 he took a prominent part in the Leslie controversy; being the author of a pamphlet setting forth the facts of the case, and also, in the general assembly, giving vent to his indignation at the proceedings against Leslie. In 1806, on the accession of the whig party to power, he received a sinecure office worth £300 a year. The death of his second son, in 1809, gave a blow to his health, otherwise indifferent, and he was unable to lecture during part of the following session; Dr. Thomas Brown, at his request, acting as his substitute. The following year Brown was appointed conjoint professor, and taught the class till his death in 1820. From 1809 Stewart lived in comparative retirement at Kinneil house, Linlithgowshire, which the duke of Hamilton placed at his service. In 1810 he published his *Philosophical Essays*; in 1814 the second volume of the *Elements*; in 1815 the first part, and in 1821 the second part, of the *Dissertation on the History of Ethical Philosophy*; in 1827 the third volume of the *Elements*; and in 1828, a few weeks before his death, the *Philosophy of the Active and Moral Powers*.

On the death of Brown, Stewart exerted himself to secure the appointment of sir W. Hamilton to the chair, but the influence used with the town council in behalf of John Wilson was overpowering; the votes stood 21 for Wilson, 9 for Hamilton. Stewart resigned his conjoint professorship on June 20, 1820.

The philosophy of Stewart was the following up of the reaction commenced by Reid against the skeptical results that Berkeley and Hume drew from the principles of Locke. Both Reid and Stewart professed the Baconian method of observation and induction, as against mere ontology, but considered that these processes of investigation could establish certain ultimate truths of a higher certainty than themselves. Hence arose the principles of common sense of Reid, in which Stewart for the most part acquiesced. Stewart also followed and improved upon Reid in that systematic exposition of all the powers of the mind, which rendered mental philosophy for the first time a subject of study, independent of metaphysical, logical, and ethical applications; although he also followed it out in all these directions with his usual perspicacity and felicity of exposition. His contributions to the philosophy of taste, in the *Philosophical Essays*, are among the best parts of his writings.

On the whole, although Stewart was not one of the most original thinkers in his department, yet, by the force of his teaching and the compass of his writings, he did more than almost any man to diffuse an interest in the speculations connected with the human mind. His collected works have been edited by sir W. Hamilton, in 11 vols., to which Prof. Veitch has contributed his biography.

STEWART, HAMILTON, b. Jefferson, Ky., 1813; established *The Civilian*, a newspaper in Texas, 1838, and conducted it in the interest of the democratic party for more than 30 years. He resided in Galveston, was mayor of the city for several years, and its representative in the constitutional convention of 1856. He favored the independence of Texas, and opposed annexation; collector at Galveston under Pres. Pierce and Pres. Buchanan; lost his position during the war. He was persistently opposed to secession for years previous to the civil war. As one of the editors of the *Galveston News* he has exerted a marked influence on the politics of the s. west.

STEWART, JOHN, b. Ireland, d. Charleston, S. C.; brother-in-law of Gen. Wayne; performed gallant service in the revolutionary war at Stony Point, and received a gold medal from congress. In 1778 he commanded a corps of light infantry at Indian Field, against Col. Emmerick's command of tories and Indians; was killed by a fall from his horse.

STEWARTON, a town of Scotland, county of Ayr, on the right bank of the Annock, five miles n.w. of Kilmarnock, and nominally a station on the Glasgow and South-Western railway, although the place called *Stewarton Station* is several miles distant from the town. Stewarton owes its prosperity to its woolen and Scotch bonnet manufactures; but it also carries on a variety of minor industries, such as carpet-weaving, Ayrshire needle-work, and the making of spindles for mills. Pop. '91, 2687.

STEWARTRY, the name which was given in Scotland to a district governed by a steward, an officer appointed by the king with jurisdiction over crown lands, and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal jurisdiction was much more extensive. The only remaining trace of this jurisdiction exists in the term *stewartry*, which in place of county is applied to the district of Kirkcudbright. Galloway was in early times rather a tributary dependency of Scotland than an integral portion of the kingdom, and retained its old Celtic proprietary, and peculiar laws and usages, which were adverse to

the introduction of a sheriffdom. It was for a long time ruled by a line of lords, who were among the most powerful feudatories of the Scottish crown. The Comyns, who in the course of time succeeded to the lordship, were overthrown and expatriated by Bruce; and it seems to have been on their forfeiture that eastern and central Galloway were erected into the present stewartry, western Galloway being already under the jurisdiction of the sheriff of Wigton. On the abolition of heritable jurisdictions in 1747, various regalities and baronies which had existed within the district were done away with, and the emancipated stewartry was placed under a steward-depute, whose functions were in every practical point of view the same as those of a sheriff-depute. Act 1 Vict. c. 39, declares that in any existing or future statute the words sheriff, sheriff-clerk, etc., shall be held to apply to steward, steward-clerk, etc.

STEWING, in cookery, a very economical way in preparing meat and fruits for food. It differs from boiling in this respect, that only a small quantity of water is used, and the heat applied is so gentle as only to *simmer* it. A stew-pan should be well fitted with a lid, and the more slowly the ebullition is carried on the better. As the small quantity of water is retained as gravy, nothing is lost. Meat prepared in this way is tender and savory, but owing partly to the richness of the gravy is not very digestible.

STEYER, a town of upper Austria, at the confluence of the Steyer and the Enns, 23 miles s.e. of Linz. It is a great seat of the iron and steel manufactures of Austria, and also carries on important manufactures of paper, woolens, and hosiery. Pop. '90, 21,499.

STHAVIRA (a Sanskrit word, meaning *old*) is, in Buddhist hierarchy, the name of the "elders" or "venerables," who, after the death of the Buddha S'âkyamuni, taught the doctrine, presided at the Buddhist assemblies, etc., and since the time of As'oka were invested with a kind of episcopal power. In the sectarian history of Buddhism, Sthavira is the name of those Arhats who did not follow the schism of the Mahâsângghikas (q.v.), but adhered to the old doctrine. According to another account, the Sthaviras are one of the four divisions of the Vaibhâshika system of Buddhism, and claim for their founder Kât'yâyana, the disciple of S'âkyamuni.—See C. F. Koeppen, *Die Religion des Buddha* (Berlin, 1857); and W. Wassiljew, *Der Buddhismus, seine Dogmen, Geschichte und Literatur* (St. Petersburg, 1860).

STICKING-PLASTER, or **COURT-PLASTER**, is best prepared in the following manner: Two solutions are first made, one of an ounce of isinglass in eight ounces of hot water, and the other of two drams of gum-benzoin in two ounces of rectified spirit. These solutions are to be strained and mixed. Several coats of this mixture, kept fluid by a gentle heat, are then to be applied with a camel's-hair brush to a piece of black silk stretched on a frame, each coat being allowed to dry before the next is applied. A layer of a solution composed of one ounce of Chian turpentine in two ounces of tincture of benzoin is then to be applied to the other side of the silk, and allowed to dry. In place of the ordinary black sticking-plaster, some persons prefer colorless plaster, or *gold-beater's skin* (q.v.).

STICKLEBACK, *Gasterosteus*, a genus of acanthopterous fishes, referred by many naturalists to the family of mailed cheeks (q.v.) (*sclerogenidæ* or *triglidæ*); by others, to a distinct family (*gasterosteidæ*), in which the first dorsal fin is represented by a number of detached spines, a single strong spine occupies the place of the ventral fins, there are only three branchiostegal rays, the gill-covers are not armed, and the body is mailed by plates on the lateral line, and destitute of scales. The species are found in fresh and brackish waters, and in the sea, in cold and temperate regions; and are small fishes, very interesting from their habits and the beauty of their colors, which they change in a remarkable manner, partly according to the colors of surrounding objects, and partly through the influence of their own passions. The **THREE-SPINED STICKLEBACK** (*G. aculeatus* or *trachurus*), having three spines instead of the first dorsal, is extremely abundant in rivers, ponds, and brackish waters in most parts of Britain and of Europe, and is sometimes also found in the sea. Sticklebacks caught in a river readily accommodate themselves to living in a salt-water aquarium. It seldom exceeds two inches and a half, or three inches in length. Cuvier and Valenciennes, Yarrell, and others, distinguish from this several other species, some of which are also British, differing in size, the armature of the sides, and other particulars (4 to 15 spines); but some naturalists are still inclined to regard them as mere varieties. The common fresh-water species are sometimes so abundant in ponds, ditches, and the still parts of rivers, as in Lincolnshire and other flat parts of the e. of England, that they are used for manure. They are seldom used as food, yet they are said to be excellent for this purpose. Oil has sometimes been expressed from them. In the aquarium, or in their native waters, their combats are very amusing. They are excessively pugnacious, particularly at the breeding season. The larger often devour the smaller, and they destroy the fry of fishes to a prodigious extent; they feed also on aquatic larvæ, and are probably of great use in preventing the excessive multiplication of many kinds of insects. Their nest-building is particularly interesting, and in them nest-building was first observed among fishes. They collect small pieces of straw or stick, with which the bottom of the nest is laid among water-plants, and these they cement together by an exudation from their own bodies which forms a thread through and round them in every conceivable direction. The thread is

whitish, fine, and silken. The sides of the nest are made after the bottom. The nest of the fresh-water stickleback is about the size of a small hazel nut. The eggs, about the size of poppy-seeds, are deposited within. The male makes the nest, into which he introduces the female for the laying of the eggs, and he afterward watches it with great care—a care not unnecessary, as the eggs are most acceptable food to any other stickleback which can get at them. See *illus.*, FISHES, vol. VI.

STIFF-NECK (known also as **WRY-NECK** or **TORTICOLLIS**) is the term commonly applied to a condition of the neck in which lateral movement of the head causes great pain, and which is due to rheumatism of the muscles lying on the side of the neck, especially the sterno-mastoid. In the great majority of cases, only one side of the neck is affected, the head being drawn more or less obliquely toward that side; but occasionally both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forward. As long as the head is allowed to remain at rest, there is merely a feeling of discomfort; but every movement is extremely painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes round the neck. In addition to the ordinary treatment of sub-acute rheumatism (q.v.), heat may be advantageously employed, either, as suggested by Dr. Wood of Philadelphia, by placing a batch of carded tow or cotton over the part, and then applying a hot flat-iron, or by the direct application of a small heated iron hammer, as recommended by Drs. Corrigan and Day.

STIGMA. See **PISTIL**.

STIGMARIA, the root of *sigillaria* (q.v.).

STIGMATA MAIDIS, the green silk of Indian corn from which an extract is made by macerating it without the use of heat. It medical use is to increase the flow of urine; it also exerts a regulating influence upon the heart, and is valuable in cases of heart disease accompanied by dropsical effusions.

STIGMATIZATION (Lat. *stigmatizatio*, a puncturing, from Gr. *stigma*, a puncture), the name applied, by the mystic writers of the Roman Catholic church, to the supposed miraculous impression on certain individuals of the "stigmata," or marks of the wounds which our Lord suffered during the course of his passion. These stigmata comprise not only the wounds of the hands and feet, and that of the side, received in the crucifixion; but also those impressed by the crown of thorns and by the scourging. The impression of the stigmata, being held to be miraculous, was regarded as a mark of the signal favor of our Lord, manifested to those who were specially devoted to the contemplation of his passion. The most remarkable example of stigmatization is that already referred to in the memoir of Francis of Assisi (q.v.), which is said to have occurred on the mountain of Alverno, upon Sept. 15, 1224, two years before the death of Francis. Being absorbed, according to the account of his biographers, in profound and rapturous contemplation of the passion of Christ, he saw, as it were, a seraph with six shining wings, blazing with fire, and having between his wings the figure of a man crucified, descend from heaven, and approach him, so as to be almost in contact. After a time the vision disappeared, but left the soul of Francis filled with reverence and awe; and on his return to calmer thought, he became aware that his body had received externally the marks of the crucifixion. His hands and feet seemed bored through with four wounds, and these wounds appeared to be filled with nails of hard flesh, the heads of which protruded and appeared upon the palms of his hands, and on the instep, while the points protruded upon the opposite side, and seemed as if clenched with a hammer. His side, moreover, presented a red wound, as though from the point of a lance, and this wound occasionally gave forth blood. These mysterious marks continued, and were frequently seen by St. Bonaventure and others during the two years which intervened between this date and the death of Francis; and they were seen by multitudes after his death.

It would be out of place here to enter into any discussion as to the origin, or the nature, of this strange phenomenon. But the case of Francis of Assisi is not a solitary one; very many others, women, as well as men, are recorded as having received all or some of the stigmata. The cases of women so visited are more numerous than those of men. A very remarkable one is that of Veronica Giuliani, in 1694, who is related to have received first the marks of the crown of thorns, and afterward those of the crucifixion; Gabriella da Piezolo of Aquila is recorded to have received the mark of the lance in 1472; Clara di Pugnny, a tertiary of the Dominican order, was similarly impressed in 1514; and Cecilia di Nobili of Nocera in 1655. Catherine di Raconisio is alleged to have been marked with the crown of thorns in 1583, and the same is related of several others, as Maria Razzi of the island of Chio, Maria Villani, Vincenza Ferreri of Valencia, and Joanna Maria of the cross, a nun of St. Clare, at Roveredo. In some cases, the visitation, although said to be accompanied with excruciating pain in the seat of the several wounds, was unattended by any external marks. Such was the case of St. Catherine of Siena, of Ursula Aguirre—otherwise known as Ursula of Valencia—of Mary Magdalen di Pazzi, and of Mechtildis von Stanz; while in other cases the wounds were in part visible, and in part invisible. Thus, Hieronyma Carvaglio suffered the pain of the wounded hands and feet without any external mark, while the lance-wound was not only visible in her side, but was reported to bleed upon every Friday, the day specially devoted to the commemoration of the passion. Blanca de Gazeran experienced the

sensation of pain in the seat of each one of the wounds, but the mark of the nail was visible upon the right foot only. The same variety of sensation is recorded in several other cases.

Most of the cases recorded hitherto are of females; and that examples of these are not wanting even in more recent times, the case of the well-known "Estatica" of Caldaro, about 40 years ago, and that of Louise Lateau, discussed quite recently, sufficiently attest. But, besides that of Francis of Assisi, instances are also recorded in which men were reputed to have received the stigmata. A Capuchin named Benedict, of Reggio, is said to have received the marks of the crown of thorns in 1602. A lay-brother named Carlo di Saeta, or Sazia, was smitten in a vision with the wound in the side. Angelo del Paz, a Franciscan of Perpignan, is related to have borne for many years all the stigmata, as also a Premonstratensian monk named Dodo, and a Franciscan called Nicholas of Ravenna. Several cases also are mentioned of men, who, without the visible or external stigmata, experienced at regular intervals the painful sensation by which the stigmata are accompanied. Many such cases are detailed by the celebrated German mystic, Görres, in his *Christliche Mystik*, vol. ii. pp. 420-456.

STILAGINA CEE, a natural order of exogenous plants, allied to *urtica*, containing about 20 known species of trees and shrubs, natives of the East Indies, Mauritius, and Madagascar. None of them are of importance.

STILBITE. See **ZEOLITE**.

STILES, EZRA, D.D., LL.D., 1727-95; b. Conn.; graduated at Yale college, 1746; tutor there, 1749-55; licensed to preach, 1749, and preached to the Stockbridge Indians; was induced by ill health and transient religious doubts to study law, 1752; admitted to the bar, 1753, and practiced in New Haven; settled pastor at Newport, R. I., 1756; on the place being occupied by the British, removed to Portsmouth, and was pastor of North church; elected president of Yale college and professor of church history, 1778, retaining the positions until his death. After the death of Dr. Daggett, 1780, he was professor of divinity, and gave lectures on philosophy and astronomy. He published *History of Three of the Judges of Charles I.*; *Account of the Settlement of Bristol*, and numerous addresses and sermons. His *Diary* and bound manuscripts, preserved at Yale, fill 45 volumes.

STILICHO, FLAVIUS, a Roman gen., the mainstay of the western empire after the death of Theodosius (q.v.) the Great, is said to have been a Vandal, and was the son of a capt. of barbarian auxiliaries in the imperial army. He rose through his military talent to high rank in the army, and Theodosius was so pleased with his rare ability, zeal, and accomplished manners, that he gave him his niece Serena in marriage. Stilicho's promotion was, however, viewed with great jealousy by Rufinus, the able but evil-minded and ambitious minister of Theodosius, and an inextinguishable feud arose between the two, which it required all the weight of the emperor's influence to repress. In 394 Stilicho departed for Rome in charge of the youthful Honorius (q.v.), who had been committed to his care, placed him on the throne of the western empire, and administered in his name the affairs of state. On the death of Theodosius, toward the close of 394, the quarrel for supremacy between Stilicho and Rufinus, the guardian of Arcadius (q.v.), became fully developed, and Alaric (q.v.), at the instigation of the latter, invaded Greece while Stilicho was engaged in chastising the invaders of the Roman territories on the Rhine and in Gaul. Stilicho, on his return, at once set out for Constantinople, and put an end to the struggle between himself and Rufinus by the destruction of his rival in 395. He then marched against Alaric, blocked him up in the Peloponnesus; but, through over-confidence, permitted him to escape across the isthmus with his captives and booty. In 398 his daughter Maria became the wife of Honorius. His old opponent, Alaric, after several inroads upon the eastern provinces of the western empire, now invaded northern Italy, but was signally defeated at Pollentia (Mar., 403) by Stilicho, who had hurriedly called in the Roman legions from Rhetia, Gaul, Germany, and even Britain. He was again defeated at Verona, upon which he retired from the empire, and Stilicho obtained the honor of a triumph and a great increase of influence and power. Stilicho's ambition now led him to attempt the introduction of his own family to the imperial succession (a statement disbelieved by Gibbon, who considers it merely as an invention of the crafty Olympius; though the great historian of the Roman empire honestly confesses to various heavy blots on the character of his hero), by the marriage of his son with the heir-presumptive Placidia, the daughter of Theodosius, and to attain this end, he made overtures of alliance to Alaric, which were gladly accepted. But the dreadful inroad of Radagaisus, in 406, at the head of more than 200,000 (some say 400,000) barbarians, who ravaged the whole country as far as Florence, compelled the great gen. of the west to shelve for a time his ambitious schemes. With a small but chosen army of veterans, aided by a body of Huns under Uldin (father of Attila), and of Visigoths under Sarus, he so harassed the invaders that they were forced to give him battle. They were soon routed. Radagaisus, who surrendered, was put to death, and his followers sold as slaves. Stilicho again resumed his pet scheme; established enmity between Rome and Byzantium by seizing on eastern Illyricum and inducing Alaric to transfer his allegiance to Honorius. But Honorius, who had been prejudiced against Stilicho by one of his officers, Olympius, refused to take eastern Illyricum from the Byzantine empire; and subsequently, by an artful harangue, he so influenced the soldiers of the army of Gaul that they rose en

masse against the partisans of Stilicho. Stilicho himself was at Bologna; and on the news of the *émeute*, his most zealous friends urged immediate action against Olympius and the Pavian rebels; but for the first time in his life, vacillation seized Stilicho, and he declined. They then, for self-preservation, turned against him, and one of them, Sarus, the Goth above mentioned, drove him out of his camp, and compelled him to flee to Ravenna, where he was soon afterward slain, Aug. 23, 408. Thus perished the last of the series of distinguished aliens, who, as emperors, warriors, or politicians, had propped up the Roman empire for 150 years, with a stern and resolute zeal equal to that of the early Romans themselves. After protecting the weak empire from formidable invasion by his own kinsmen, administering its affairs with remarkable ability, moderation, and integrity, and restoring its old heroic glory to the imperial arms, Stilicho received the reward which alone an effete and conceited people can be expected to bestow; and three months after his death, Alaric and his Visigoths were at the gates of Rome.

STILL is the apparatus employed for the distillation of liquids, and consists of the copper boiler or *alembic* (see DISTILLATION), in which is contained the fermented liquor whose vapors are to be distilled; of the *neck* or *head*, a pipe which conveys the vapor generated in the boiler into the worm; and of the *worm*, a coiled metal tube which is packed in a vessel called a *refrigeratory*, fitted up in such a manner that the cold water which is poured in at the top comes in contact as extensively as possible with the outside of the tube, and exercises a condensing action upon the vapor which it contains. The vapor thus condensed in its passage through the worm, makes its exit in drops, or in a small stream, into a vessel called the *recipient*, and may be redistilled or not as is required. The various forms of stills are extremely numerous, almost each species of spirit possessing its own form of still, but they all conform to the general description above given.

STILL, JOHN. An English prelate, born at Grantham, Lincolnshire, about 1543. He was educated at Christ's College, Cambridge. He became successively Margaret Professor of Divinity at Cambridge (1570), Prebendary of Westminster (1573), Master of St. John's College, Cambridge (1574), Archdeacon of Sudbury (1576), Master of Trinity College, Cambridge (1577), and Bishop of Bath and Wells (1592-93). He died in 1607. He is supposed to be the author of *A Ryght Pithy, Pleasant and Merie Comedie, intytuled Gammer Gurton's Needle*, the third English comedy, containing the first good English drinking ballad of which the chorus runs, "Backe and side go bare, go bare," etc., for which see Washington Irving's sketch of "Little Britain" in his *Sketch Book*.

STILLÉ, ALFRED, b. Philadelphia, 1813; an American physician. After graduating at the university of Pennsylvania in 1832 he became resident physician of the Philadelphia hospital, and in 1839-41 of the Pennsylvania hospital. He attended medical lectures in Paris and other European cities, and in 1844 became lecturer on pathology and practice of medicine to the Philadelphia association for medical instruction. In 1849 he was made physician to St. Joseph's hospital, soon afterward professor in the Pennsylvania medical college, and from 1864 to 1884 he lectured in the university of Pennsylvania. He wrote among other books *Elements of General Pathology and Therapeutics* and *Materia Medica*.

STILLÉ, CHARLES JANEWAY, LL.D., b. Philadelphia, 1819; graduated from Yale college in 1839; was made professor of English literature in the university of Pennsylvania, 1866; and provost, 1868, from which office he retired in 1880. He has published *How a Free People Conduct a Long War* (1862); *Northern Interest and Southern Independence* (1863); *The Historical Development of American Civilization* (1863); *Memorial of the Philadelphia Central Fair for the U. S. Sanitary Commission*; *History of the U. S. Sanitary Commission* (1866); *Studies in Mediæval History*, 1880.

STILLINGFLEET, EDWARD, bishop of Worcester, was b. April 17, 1635, at Cranbourne, in Dorsetshire. He received his early education at the grammar-school of his native place, and in 1648 became a student at St. John's college, Cambridge. He took his degree as master of arts; and in 1653 succeeded in obtaining a fellowship. For some years after leaving college he was occupied as a private family tutor; and in 1657 he was presented to the rectory of Sutton. In 1659 he came before the world as an author in the work entitled *Irenicum, or the Divine Right of Particular Forms of Church Government Examined*. The views here maintained savored somewhat more of latitudinarianism than could be pleasant to the high church party, and he afterward saw reason to modify them. His next performance was the *Origines Sacre, or Rational Account of the Christian Faith, as to the Truth and Divine Authority of the Scriptures*, a work which made his reputation, and is still had in estimation as one of the most masterly treatises extant on the subject of which it treats. In 1664 appeared his *Rational Account of the Grounds of the Protestant Religion*, a defence of the church of England from the charge of schism in its separation from that of Rome, which was received with great favor, and led to the preferment of its author. In 1665 the earl of Southampton presented him to the rectory of St. Andrews, Holborn; he was also appointed preacher at the rolls chapel, and shortly after lecturer at the temple, and chaplain in ordinary to Charles II. In 1670 he became, by favor of the king, canon residentiary of St. Paul's cathedral, and in 1678 was preferred to be dean of the same. In the court of ecclesiastical commission instituted by James II., Stillingfleet declined to act; and after the revolution of 1688 he received, in final acknowledgment of his services to the Protestant cause, his appointment to the bishopric of Worcester. He died at Westminster on Mar. 27, 1699.

Stillingfleet's chief works, besides those mentioned, were the *Origines Britannicæ*, or *Antiquities of the British Churches*, and a bulky volume entitled *The Unreasonableness of Separation*, in reply to an attack made upon him by Howe and others. Throughout, he was besides almost constantly engaged in religious controversy, on the one hand with the adherents of the church of Rome, and on the other with the Nonconformists.

STILLING-GIA, a genus of plants belonging to the natural order *euphorbiaceæ*, and named in compliment to Dr. Stillingfleet, an English botanist. The generic characteristics are: flowers monœcious; males aggregate; calyx cup-shaped, crenulate, or bifid; stamens two, inverted; filaments united at the base; anthers opening outward; female flowers solitary; calyx tridentate or trifid; ovary sessile, three celled, each cell with a single ovule; style short, thick; stigmas three, simple, spreading; capsule globose, tricoccus; cocci single-seeded. The species are milky trees or shrubs of the tropical parts of Asia and America, and of the islands of Bourbon and Mauritius. The leaves are alternate, petiolate. The *stillingia sebifera* is the famous tallow tree of China, which at one time was introduced into various European colonies in the East and West Indies, and is often met with in hot-houses. It grows in China on the borders of rivulets, and is also cultivated. It is about as high as a pear-tree, having a trunk and branches like the cherry, and foliage resembling that of the black poplar, but which turns red in the autumn. The fruit is the part from which the Chinese obtain the tallow.

STILL-LIFE is the name applied to that branch of art which concerns itself with the representation of lifeless objects, such as dead animals, fruits, flowers, vases, and house-furniture.

STILLMAN, SAMUEL, D.D., 1738-1807; b. Philadelphia; ordained in Charleston, S. C., as an evangelist, 1759; preached for a time at James island; removed to Bordentown, N. J., 1760; settled, 1765, as pastor of the First Baptist church, Boston, remaining till his death. In 1764 he was one of the incorporators of Brown university, and elected fellow the following year. He was distinguished for patriotism, and was a delegate to the Mass. constitutional convention, 1788. He published patriotic, masonic, and biographical discourses, and "election" sermons.

STILLMAN, WILLIAM JAMES, b. N. Y., 1828; an artist and littérateur; graduate of Union college, 1848; studied landscape painting in New York and France. He was art editor of the *Evening Post*, 1853-4, and also in 1883. He was U. S. consul at Rome, 1861-65; at Crete, 1865-69; author of a number of works on Greek archæology and art.

STILLWATER, city and co. seat of Washington co., Minn.; on the St. Croix river and lake, and the Chicago and Northwestern, the Chicago, Milwaukee, and St. Paul, the Chicago, St. Paul, Minneapolis, and Omaha, the St. Paul and Duluth, and the Wisconsin Central railroads; 18 miles n.e. of St. Paul. North of the city is the St. Croix boom, through which about 300,000,000 feet of pine logs are passed annually. The city is the seat of the state penitentiary, and has a high school, public library, hospital, opera houses, a bridge across the head of the lake, electric lights and street railroads, water-works supplied chiefly from springs, national and savings banks, about 12 churches, and daily and weekly newspapers. The principal industries are those connected with lumbering. There are many points of local interest, including the Sioux-Chippewa battlefield, painted rocks, and picturesque bluffs. Pop. '90, 11,260.

STILTED ARCH, an arch in which the impost molding is placed at some distance below the springing of the arch.

STILTS (Dutch, *stelts*), are long sticks or crutches on which a person may stand when walking, in order to increase the length of stride. In the western part of Landes, in south-western France, they are of great use to a few poor people who live there on great plains made up of swamps and sand dunes, and whose sole occupation is the care of small flocks of sheep or herds of swine on these plains. For this purpose they use long stilts that are strapped firmly to the leg, while in the hand they carry a long pole to assist them in walking. This pole also has a cross-piece on one end something like a crutch, and by putting it behind him on a slant, a person may use it as a stool, to sit upon and rest, and when seen at a distance, look not unlike a huge tripod, or three-legged stool. Women use these stilts as well as the men, and may often be seen sitting in this manner and knitting as they watch the flocks.

STILTS, or **STILT PLOVERS**, the common names of a genus, *himantopus*, of the snipe family, *scelopacidae*, of the order *grallatores*. The stilts have long, slender bills, cylindrical, flattened at the base, compressed at the point; both mandibles channelled to the extent of half their length from the base; nostrils lateral, linear; tarsi very long and slender; toes three, before; nails small and flat; wings very long, the first quill-feather the longest. *Himantopus melanopterus* (charadrius *himantopus* of Linn.) *cavaliere grande Italiano* of the Italians, *Schwarzflügelige strandreuter* of the Germans, long-legged plover, stilt, and longshanks of the English, has face, neck, and all lower parts pure white, slightly rosy on the breast and belly; top of head and neck black, with white spots; back and wings black, glossed with green; tail ash-color; bill black; iris crimson; feet vermilion; length from point of bill to end of tail 14 in., and to the claws about 19 in. The very old males have the nape of neck and occiput quite white. Female smaller

than male, and having no green gloss on shoulders; general tint browner. Six species of *himantopus* are recognized by G. R. Gray as inhabitants of various parts of the world. One species is found in America, ranging from the great lakes to Paraguay. It is about 14 in. long, the bill and tail each forming 3 in., leaving 8 in. for the body: tarsi 4 in., rather longer than the tibiae; glossy black on back, wings, top of head, and neck. White above, beneath, and in front of the eyes: bill black; legs red. It is found along the sea-coast, and also along lakes and rivers far inland; gregarious, in flocks of twenty and thirty, or more. They frequent muddy flats with reedy margins, making nests of grasses. Four eggs is the most frequent number laid for a brood; they are rather large, of an ochrey color, with brown blotches and streaks. The birds are graceful walkers, with long, measured steps. They live on small fishes and their eggs, and aquatic insects. Although the bird is widely distributed it is rare. Its visits are accidental and uncertain. It is scarce in the northern portion of Europe, but its wide range makes up for its local scarcity.

STIMPSON, WILLIAM, 1832-72; b. Mass.; studied medicine, and made a specialty of conchology. Among his writings, besides many papers in the *Smithsonian Contributions*, and scientific periodicals, are *Revision of the Synonymy of the Testaceous Mollusks of New England* (1851); *Notes on North American Crustacea* (1859); and *Researches upon the Hydrobiinae and Allied Forms* (1865).

STIMULANTS may be defined as agents which produce a sudden, but not a permanent, augmentation in the activity of the vital functions. They give increased energy to the circulatory and cerebro-spinal nervous systems, the primary effect being probably on the nervous system, while the circulation is only secondarily affected. In their mode of action they resemble tonics (q.v.) in some respects; thus immediately after their administration a feeling of increased power is produced, which, however, is not permanent, and is almost always followed by a corresponding depression of vital power; their effects are, however, more immediate than those of tonics. Many of these agents, as, for example, alcohol and the ethers, are closely allied to narcotics, their secondary effect, if given in sufficiently large doses, being to produce sleep, and even coma. The following are the most important of the general stimulants: 1. *Alcohol*, in the various forms of spirits and wines. As a stimulant, alcohol is employed in medicine to support the vital powers in the advanced stages of fevers, particularly those of a low or typhous character; and it is of service in flatulent colic, in some forms of indigestion, in vomiting, and in fainting. Its almost universal use in inflammatory diseases occurring in persons of broken-down constitution has recently been advocated by a special school, of which the late Dr. Todd may be considered a representative. In cases of severe uterine hemorrhage and in some forms of fever, it may be given in very large quantity. According to Neligan, in the fever which proved so fatal to the British legion in Spain in the year 1835, some of the physicians prescribed as much as 32 ounces of brandy (a pint and a half) in 24 hours. 2. *Ammonia*, either in the form of *solution of ammonia*, or *liquor ammonia*, or as *carbonate of ammonia* is a general stimulant, whose action is rapid, but temporary. It is of special use in the advanced stages of continued fever, in the eruptive fevers when the rash has receded (especially in scarlatina), and in the latter stages of pneumonia. It is the best internal stimulant to employ in profound intoxication, and in cases of poisoning by sedatives; and as an external stimulant, the vapor is inhaled in cases of fainting. The solution (which must not be confounded with the *strong solution of ammonia*) may be given in doses of from 5 to 30 minims, diluted with two ounces of water, mucilage, or any bland fluid. The *carbonate* (formerly known as the sesquicarbonate, which in reality it is) may be given in doses varying from 3 to 10 grains in pills or in cold water. The *aromatic spirit of ammonia*, containing both ammonia and its carbonate, is an excellent and agreeable stimulant in fainting, hysteria, flatulent colic, etc., in doses of from half a dram to a dram, taken in water or camphor mixture. 3. *Cajeput oil*, in doses of from 2 to 6 drops on a lump of sugar, or rubbed up with sugar, is a powerful diffusible stimulant, admirably suited for cases of flatulent distention of the stomach and intestines. 4. *Ether* (known also as *sulphuric ether*) acts as a general diffusible stimulant; but its effects, which are rapidly produced, are very transient. It is chiefly employed as a stimulant in spasmodic and nervous affections unaccompanied by inflammation, as "in cramp of the stomach, in spasmodic or flatulent colic, in nervous palpitations, in hiccough, in nervous headache, during a paroxysm of spasmodic asthma, in aphonia, etc. It is also administered frequently with good effect in the advanced stages of fever, when the twitching of the muscles, known as *subsultus tendinum*, and hiccough are present; and as an immediate stimulant in fainting and asphyxia."—Neligan's *Medicines*, etc., 6th ed. p. 452. It is usually given in doses of about a dram in some aromatic water. To these more important stimulants may be added camphor, ginger, horse-radish, the preparations of lavender, of the mints, etc. It must not be forgotten that electricity, galvanism, and magnetic electricity operate on the animal system either as general or local stimulants, according to the manner in which they are applied. See ELECTRICITY, MEDICAL.

STINDE, JULIUS ERNST WILHELM, German author, was born at Kirch-Nüchel in Holstein, Aug. 28th, 1841. Having studied chemistry and natural philosophy, he was for some years after 1863 employed as a chemist in Hamburg. He then accepted the editorship of the *Hamburger Gewerbeblatt*, and finally devoted himself entirely to litera-

ture, at first writing principally upon subjects in natural philosophy. Beside numerous contributions to periodical literature, he published: *Blicke durch das Mikroskop* (1869); *Alltagsmärchen: Novellen* (1873); *Naturwissenschaftliche Plaudereien* (1873); *Die Opfer der Wissenschaft* (under the pseudonym Alfred de Valmy (1879); *Aus der Werkstatt der Natur* (1880, 3 vols.); *Das Rauchen* (1881); *Waldnovellen* (1881; 10th ed., '89); *Die Wandertruppe, oder, das Dekameron der Verkannten* (2nd ed., 1886); *Die Perlenschnur* (1887). A series of several volumes, purporting to be written by one Wilhelmine Buchholz, and which dealt with the life of the middle classes in Berlin became very popular, both in the original and in the English translations, and brought his name prominently before the general public. These volumes, some of which ran through fifty or more editions, include: *Die Familie Buchholz* (1884); *Die Buchholzen in Italien* (1883); *Frau Buchholz im Orient* (1888); *Frau Wilhelmine Buchholz' Memoiren* (1895), and *Hotel Buchholz Ausstellungs-erlebnisse* (1896). Stinde's contributions to dramatic literature include several comedies in the *plattdeutsch* dialect, which proved very popular at the Karl Schultze theatre in Hamburg, such as *Hamburger Leiden*; *Tante Lotte*; *Eine Hamburger Köchin*; *Die Familie Karstens*; *Die Blumenhändlerin von St. Pauli*; etc., also *Prinzess Tausende schön*, *Prinz Unart*, and *Ihre Familie* (written jointly with G. Engels). Stinde's Buchholz series are the favorite light reading of Prince Bismarck.

STING FISH. See WEEVER.

STING RAY, *Trygon*, a genus of cartilaginous fishes, of the order *raia* (see RAY) and family *trygonidae*. In this family the tail is long and slender, the eyes on the upper (dorsal) aspect, and in the genus *trygon* the tail is armed with a strong spine notched on both sides. The tail has either no fin, or a merely rudimental one. Only one species of sting ray occurs in the British seas (*T. pastinaca*), popularly known as the fire flaire. It is found in the Mediterranean, and thence to the northernmost parts of Europe. It resembles a skate in general appearance. The flesh is remarkable for its redness of color, and is not esteemed. The sting ray is dreaded from the power which it has of using its muscular and flexible tail as a weapon, twisting it round the object of attack, and inflicting severe lacerated wounds with the serrated spine. These wounds often cause great inflammation, whence a notion has been prevalent from ancient times that the sting is charged with venom; but of this there is no evidence. Other species of sting ray are plentiful in the warmer parts of the world, and they are everywhere dreaded. The spine is used by the savages of the South Sea islands to point their spears.

STINK-POT, in warfare a shell, often of earthenware, charged with combustibles, which, on bursting, emit a foul smell and a suffocating smoke. It is useful in sieges for driving the garrison from their defenses; also in boarding a ship, for effecting a diversion while the assailants gain the deck. The stink-pot is a favorite weapon of the Chinese. Under the more elegant title of Asphyxiated shell, the French and other modern nations have experimented considerably on this mode of harassing an enemy.

STINK-STONE, or SWINE-STONE, a kind of marble or limestone remarkable for the fetid urinous odor which it emits when rubbed. It contains a little sulphur.

STINK-TRAPS, a name given to certain very useful forms of drain-openings, which while allowing liquids to run down, prevent the escape of noxious gases. They are made of iron or earthenware, in a great variety of forms, but on one very simple principle, there being a curved or siphon pipe below the grating or grid which always retains sufficient water to prevent the outward passage of the gases.

STINK-WOOD, *Oreodaphne fatida*, a tree of the natural order *lauraceæ*, a native of the cape of Good Hope, remarkable for the strong disagreeable smell of its wood, which, however, is hard, very durable, takes an excellent polish, and resembles walnut. It has been used in ship-building.

STINT. See SANDPIPER.

STIPA. See FEATHER GRASS.

STIPE, in botany, a term used to designate the stem of palms and tree-ferns.

STIPEND, the provision for the support of the parochial clergy of the church of Scotland. It consists of payments in money or grain, or both, made out of the teinds or tithes of their parishes. The teinds, originally the tenths of the produce of the lands drawn in kind, have become converted into a separate estate, held under a liability for stipend. In a majority of cases they have been purchased at a valuation by the owners of the lands to which they belong, stipends having first been "modified" from them, and they are held under the burden of augmenting the minister's stipend to the extent of their value. Sometimes they have passed in to the hands of titulars, i.e., grantees from the crown and their successors, or belong to colleges and hospitals, to all of whom payment of tithes is made by the proprietor of the lands according to a valuation or composition; and the teinds formerly held by bishops or other dignified clergy are in the hands of the crown. In 1617 a commission was appointed by James VI. to modify stipends to the clergy from the parochial teinds. The provision was at first limited to a maximum of 10 chalders of victual or 1000 merks (£55 11s. 1d.) per annum and a minimum of 5 chalders or 500 merks (£27 15s. 6d.); but the minimum was raised in 1649 to 8 chalders, or 3 chalders and money for the other 5, at a conversion not ex-

ceeding £100 Scots or beneath 100 merks for each chaldar; and it has been the practice to allow a further sum to the minister to meet the expense of communion elements. The power of assigning, modifying, and localing stipends, has, since the union, been possessed by the judges of the court of sessions, sitting as a court of commission of teinds. When the existing stipend of a clergyman is considered insufficient, and there remains any free teind (i.e., teind as yet unappropriated for stipend), the court have it in their power to award him out of it what augmentation they deem suitable. But by act 48, Geo. III. c. 138. no stipend can be augmented a second time till after the lapse of 20 years from a previous augmentation. The augmented stipend is modified in vicual; but the minister receives it not in kind, but in value, according to the highest fiars (q.v.) prices of each year. By 50 Geo. III. c. 84, £10,000 annually was set apart from the revenue for the purpose of raising all stipends to £150, where the teinds of the parish did not provide that sum. Act 5 Geo. IV. c. 72 makes certain provisions out of the public revenue for those clergymen who have neither manse nor glebe, or who have a manse but no glebe, or a glebe but no manse, and whose stipends do not exceed £200 a year.

STIPULATION, in Roman law, was an agreement attended with certain solemnities. The word is used in English and Scotch law only in a popular sense, to denote any distinct matter expressly agreed upon by the parties to an agreement or deed.

STIPULE, in botany, a leafy appendage at the base of the leaf-stalk in many plants. Sometimes the stipule is solitary; but frequently there are two, one on each side of the leaf-stalk. They are of very various form and character, often very dissimilar to the leaf with which they are connected. In some plants, they are large, enveloping the young leaf, but soon falling off; in many, they are deciduous; but in many they are as permanent as the leaf itself. Their presence or absence, their deciduous or persistent character, and other peculiarities which they exhibit, form distinctive characteristics not only of species and genera, but of natural orders. They are generally green, like leaves; but sometimes membranaceous. In some plants, they assume the form of spines; in *cucurbitaceæ*, that of tendrils. Organs of the same nature with stipules appear at the base of the leaflets of some compound leaves.

STIRLING, a market, t. river-port, and royal, parliamentary, and municipal burg, capital of the county of the same name, stands on the s. bank of the Forth, 35 m. n.w. of Edinburgh by railroad. Like Edinburgh, to which city it bears, in its main features, a striking resemblance, it no doubt owes its origin to the strong natural fortress of its Castle Hill. From this hill, covering the declivity which slopes n. and eastward to the plain, extends the oldest part of the town, around which are numerous streets; while many villas have risen in the environs. The Castle Hill, which rises gradually from the e., and fronts the w. with a steep, precipitous wall of basaltic rock, overlooks the beautiful and fertile *carse*, or flat, which lies along the banks of the Forth. Among the more prominent public buildings and institutions are the East and West Churches—the former erected by James IV. about 1494, the latter built at a later period; and “Mar’s Work,” an incomplete structure, built by the earl of Mar, regent of Scotland, who died in 1572, when the building was in progress. This architectural fragment is richly ornamented. In the more ancient quarters, one or two pleasing specimens of old Scotch domestic architecture may still be seen. Of these “Argyle’s Lodging,” with its pinnacled round towers and decorated windows, is the chief. It is now used as a military hospital. The town-house is surmounted with a spire, and has the old jail attached. It contains the jug or standard of dry measure which was given to the keeping of Stirling by the Scottish parliament; while Linlithgow is said to have received the flint; Edinburgh, the ell, etc. The new jail is a handsome building. Cowan’s hospital, founded in 1639, is an object of interest. There are also an atheneum, corn exchange, and numerous excellent schools. A magnificent art institute, called the Smith institute, in honor of the founder, was opened in 1874. The importance of Stirling in early times was due to its situation and its defenses. At the head of the navigation of the Forth, when there were no regular ferries, Stirling was the key to the Highlands, and the possession of its strength and its means of communication between n. and s. was of the greatest importance. The town, besides, was strongly fortified by both nature and art. The ancient bridge of Stirling, the age of which is unknown, but which was in existence in 1571, is composed of four arches, and was defended at each end by gates and towers. This bridge was, until quite recent years, the only one by which wheeled carriages could cross the Forth. Vessels of 150 tons can reach the port of Stirling, but its commerce by river is now of less importance than before the days of railroads. Stirling is a central railroad station, and the means of communication in every direction are ready and abundant. The rich agricultural, mining and manufacturing districts around are to a great extent the basis of the prosperity of the town itself. Manufactures of ropes, malt, leather, soap, and mineral oils are carried on. The town unites with the Dunfermline burghs in sending a member to the house of commons. Pop. ‘81 of parl. burgh, 16,001.

Stirling (formerly *Stryvelyne*, or *Estrivelin*) is one of the most ancient and historically important towns of Scotland. It is of unknown antiquity; and there is no record from which the date of the foundation of even the castle can be determined. It must have been a frontier fortress from the earliest times. Alexander I. died in the castle in 1124. In the vicinity, the battle of Stirling was fought in 1297. See WALLACE. The town was taken by Edward I., after a siege of three months, in 1304. In the vicinity, at Ban-

nockburn (q.v.), the famous battle of that name was fought in 1314. The castle was the birthplace of James II. and of James V. James III. built the parliament house in the castle, and otherwise improved and embellished the fortress. James V. built the palace, the walls of which are profusely covered with grotesque ornamentation. In the older part of the castle is the "Douglas Room," in which William, earl of Douglas, was assassinated by James II. In 1651, after the battle of Dunbar, the castle was taken by Monk; and it withstood a siege by the Highlanders in 1745. The view from the towers of Stirling castle is unsurpassed in beauty. Westward, the rich vale of Menteith stretches away to the Highlands, where Ben Lomond, Ben Venue, Ben A'an, and Ben Ledi close the scene. The glittering "links" of Forth are seen in the carse of Stirling, surrounded by fertile fields and luxuriant woods; the Abbey Craig, crowned by the Wallace monument, rises boldly on the n.; while on the e. are seen the picturesque ruins of Cambuskenneth Abby.

STIRLING, EARL OF. See ALEXANDER, WILLIAM.

STIRLING, JAMES, mathematician, was born in Stirlingshire, Scotland, in 1692. He was educated at Glasgow and Oxford, and went to Venice as professor of mathematics. While here he published his *Lineæ Tertii Ordinis Newtonianæ, sive*. On account of his discovery of a trade secret of the glass-makers of Venice, he was obliged to leave Venice, and returned to London, where he was engaged in teaching for many years, and where in 1730, he published his most important work, *Methodus Differentialis, sive Tractatus de Summatione et Interpolatione Serierum Infinitarum*. He died in 1770.

STIRLING, JAMES HUTCHINSON, LL.D.; b. Glasgow, 1820; studied art and medicine at the Glasgow university. He practiced medicine for some years in South Wales, but in 1857 visited the continent, while there and after his return to England pursued an extensive course of philosophical study. He has published *The Secret of Hegel*, a translation of Schwegler's *History of Philosophy*; *As Regards Protoplasm*; *Lectures on the Philosophy of Law*; *Philosophy and Theology* (1890); *Workmen and Work* (1894), etc.

STIRLING, Sir THOMAS, 1735-1808; b. Scotland; commanded a company of royal highlanders, 1757. In 1758-59, he served under Abercrombie and Amherst; was present at the siege of Niagara, and joined in the expedition to Lower Canada, 1760. In 1766 he was on duty in Philadelphia, leaving his station at fort Chartres. He was made lieutenant, 1771, was prominent in all the great battles of the revolutionary war, and rose through successive grades to general, 1801. He was knighted in 1796.

STIRLING, Sir WILLIAM. See MAXWELL.

STIRLINGSHIRE, a county of Scotland, forming the border between the Highlands and Lowlands of the country, is bounded on the n. by Perthshire, and by the river and firth of Forth. Area, 467 sq. m.; pop. in '81, 112,443. A considerable part of Stirlingshire is occupied by the carse of Stirling and Falkirk, which were formerly covered for the most part with unproductive moss. On the removal of the moss-soil, part of which was floated off into the Forth by the agency of running water, a rich clay-soil, of various depths, from a plow-furrow to 20, and even 30 ft., was reached, and is now cultivated with the most marked success. The chief elevation is Ben-Lomond (q.v.), in the north-west. The chief rivers are the Forth (q.v.), the Carron—navigable for small vessels to Carron-shore—and the Endrick. Loch Lomond (q.v.) is the only important lake in the county. Stirlingshire is remarkable for its mineral stores, especially ironstone, which is wrought on an extensive scale at Carron (q.v). Woolen goods, etc., are largely manufactured, especially at Alva, Bannockburn, and in the neighborhood of Stirling (q.v.).

STIR RUPS (naval) are eyes of rope pendent from the yards, and supporting several portions of the tackle connected with the management of the sails.

STITCH in the side is the popular and expressive name applied to the pain felt in pleurisy. It occupies a point or small spot on a level with, or just beneath the breast on the left side; and patients state that they feel as if some sharp stabbing instrument were being driven in at that spot, whenever the act of inspiration goes beyond a certain limit. It is termed in French *Point de Côté*. See PLEURISY. A simple modification of stitch is by no means uncommon, if a person take exercise shortly after partaking of a full meal. The pain in this case is seated lower in the side, and is usually removed by stooping. Hence the popular remedy for this pain is to make a cross upon the foot.

STITCH'WORT, *Stellaria*, a genus of plants of the natural order *caryophylleæ*, having a calyx of 5 leaves, 5 deeply-cloven petals, 10 stamens, 3 styles, and a many-seeded capsule opening with six teeth. The species are numerous, and several are very common in Britain, annual and perennial plants, with weak stems and white flowers, which in some are minute, and in others are large enough to be very ornamental to woods and hedgebanks, as in the wood stitchwort (*S. nemorum*) and the greater stitchwort (*S. holosta*). To this genus the common chickweed (q.v.) is generally referred.

STITH, WILLIAM, 1689-1755, b. Va.; educated in England, and took orders in the church. He was appointed master of the grammar school of William and Mary college, Va., in 1731, was chaplain of the house of burgesses in 1738, and president of William and Mary college, and rector of Henrico parish from 1752 to his death. He wrote a

History of the First Discovery and Settlement of Virginia, 1747, in accuracy of detail not exceeded by any American historical work.

STIVER, a coin of Holland, equivalent to about two cents, being the $\frac{1}{20}$ of a guilder or gulden. See FLORIN.

STOAT. See ERMINE.

STOBE'US, JOANNES, an ancient Greek writer, native of Stobi, Macedonia. It is thought that he lived about 500 A.D., but almost nothing is known about his personal life. He made two extensive works of selections from several hundred Greek authors. These collections were called the *Eclogæ* and the *Anthologion*, and by them many utterances of ancient writers have been preserved to us, which would otherwise have been lost.

STOCK, or STOCK GILLYFLOWER, *Matthiola*, a genus of plants of the natural order *crucifere*, having cylindrical or compressed pods, and a stigma consisting of two upright appressed plates, the outer side of which often rises into a knob or horn. The species are herbaceous or half-shrubby, natives of the countries around the Mediterranean sea, most of them thickly clothed with white or grayish stellate hairs; the flowers in racemes, and generally beautiful and fragrant. Some of the species have long been much cultivated, and many fine varieties have been produced by cultivation. *M. incana*, a very rare and even doubtful native of England, is probably the parent of the greater number of the cultivated kinds with hoary leaves, known as Brompton stock, etc.; while those with smooth leaves, called ten-week stock, German stock, etc., are referred to *M. annua*, *M. glabra*, and *M. fenestralis*, which, perhaps, are mere varieties of one species. The sandy shores of Wales and of Cornwall produces a species, *M. sinuata*, the large purple flowers of which are fragrant only at night—a characteristic also of several other species. Stocks are always raised by gardeners from seed, which even the double kinds often produce, a multiplication of the petals having taken place without loss of the parts of fructification. Of the seedlings, however, some produce double and others single flowers, so that only some gratify the cultivator. The hoary-leaved stocks are generally treated as biennials, although, in reality, they may almost be reckoned perennial; and it is not desirable that they should flower in the first year, as the plants become stronger when they remain without flowering till the second year, and produce richer racemes of flowers. The smooth-leaved stocks are treated as annuals.—The beautiful little annual called Virginian stock does not belong to this genus, although it is of the same natural order. Its habit is indeed very different. It is *Malcolmia maritima*, and notwithstanding its popular name, is a native of the shores of the Mediterranean. It has become one of our most favorite flowers, almost rivaling mignonette, and is all the more esteemed because it grows well in the little garden plots which are exposed to the smoke of towns.

STOCKBRIDGE, a town in Berkshire co., Mass.; on the Housatonic river and the New York, New Haven, and Hartford railroad; 17 miles s. of Pittsfield. It was incorporated in 1739, and contains the villages of Stockbridge, Curtisville, and Glendale. There are a high school, public library, Williams academy, national bank, Goodrich memorial bridge, Jonathan Edwards monument, chimes tower, old Indian mission house, and several parks. It is a popular summer resort, with beautiful scenery, including the river, lake Averic, lake Mahkeenac, and Monument mountain. Pop. '90, 2132.

STOCKBRIDGE, HENRY, b. Mass., 1822; graduate of Amherst college, 1845; studied law and was admitted to practice in Maryland, 1848. He favored the union cause in the late civil war; member of the state legislature, 1864. He was a member of the constitutional convention which met to decide the question of the abolition of slavery in the state, was active in securing the adoption of the constitution framed by its members, and defended it before the courts. It was by his exertions that the indentures of apprenticeship which threatened to take the place of slavery were omitted from the statutes, and enfranchisement secured, without possibility of evasion, to the colored children of Maryland. He d. Mar. 11, 1895.

STOCK-BROKER, or SHARE-BROKER, a person employed in buying and selling stock in the public home and foreign funds, also in stock or shares of joint-stock companies. In most of the principal towns stock exchanges are established, and the stock or share brokers are members of such exchanges, and are bound to transact business in terms of the rules and regulations of the exchange to which they belong. In London, in addition to ordinary brokers, there are what are called sworn brokers, who require a license from the city corporation, for which certain fees are exacted, before being entitled to transact business in the public funds. In the provincial exchanges the brokers require no license, nor do they pay any fee to government or other authorities. The charge for brokerage or commissions varies from $\frac{1}{2}$ in consols to $\frac{1}{2}$ per cent in railway stocks; the rates for shares being charged according to the amount of the share, and in accordance with a scale adopted by the stock exchanges.

STOCKDOVE, *Columba anas*, a wild pigeon, native of Europe; a beautiful gray bird with a burnished metallic purple breast, scarlet eyes, orange-colored bill, and red legs. It is about 14 in. in length from bill to end of tail. It is named from its habit of making its nest in hollow stumps or tree stocks.

STOCK EXCHANGE, an organization of persons whose business it is to buy and sell stocks, bonds, and other securities, municipal, state, or national; or of corporations engaged in mining, transportation, banking, or commerce, in open market at specified times, and under strict rules. The New York stock exchange was first regularly organized in 1817, but its records were destroyed in the great fire of 1835. A similar organization existed in Philadelphia prior to that in New York, after which the latter was patterned. The stocks dealt in were U. S. stocks, state stocks, and city bank and insurance stock. By 1830 railroad stocks had come into the market—Mohawk, Catskill, Harlem, etc.; and the Morris and Delaware and Hudson canals. In 1823 the initiation fee of the New York stock exchange was \$25; in 1827, \$100; and in 1833, \$150. At present a seat in the board is worth \$25,000. The number of members is 1100; and in case of the death of a member, his seat is sold, and the sum received paid to his heirs—less any dues or unfulfilled contracts standing against his name. The regulations are very stringent, some of them involving for their breach expulsion and loss of seat without indemnity. A gratuity fund pays to the heirs of any broker who dies in good standing, the sum of \$10,000, without deductions. About 200,000 shares of stock change hands daily, and the operations sometimes cover \$50,000,000 value of securities handled. A committee on arbitration settles disputes among members. On the failure of a member of the stock exchange, his assets (stock, bonds, and other securities) are sold at public sale “under the rule,” and the proceeds divided among his creditors. The processes of sale in the exchange, though apparently complicated, and impossible for the uninitiated to understand, are in reality simple enough. A call of the list of stocks is made twice a day, as a matter of form; and the government, state, and railroad bonds are called in a room specially devoted to that purpose. But the sales are made by the brokers themselves, each one offering whatever stock he has to sell, crying it aloud, number of shares and price; or naming the price he offers for a stock, if buying. These cries, which issue from several hundred throats at the same time, are readily distinguished and understood by the brokers, and the transactions are closed and noted accurately. Persons employed for the purpose gather and record as many of these sales as possible, and these are sent by the telegraph instrument to all the different offices and places of resort where connecting instruments are kept, where speculators and investors can watch the market, and knowing the fluctuations and indications as they occur, can give their orders to their brokers intelligently. The record of transactions is abbreviated both as to the name of the stock and the nature of the sale. Thus, “L.S. 400:125:s.60,” means 400 shares of Lake Shore and Michigan Southern railroad stock at \$125, to be delivered at the seller's option any time within 60 days. The option is with the buyer if recorded “b.60;” the number of days of course varying according to agreement. The letters *ex.* mean less dividend. Applied to bonds, *c.* means coupon, and *r.* registered; *o.b.* stands for delivery at the opening of the books of transfer. Stock is bought either for its full value in cash, or on a *margin*. In the latter instance, the client deposits with his broker 10 per cent. of the par value of the stock, thus securing the latter against a loss, since he can sell if the stock falls to the point which the margin covers; or can call for more margin, selling if the client declines further risk. Those who contract to deliver stock at a future day at a fixed price are said to *sell short*, and are technically called “bears,” because they desire to squeeze or depress the market. “Bulls,” on the contrary, buy stock for a rise, and are called “long” of the stock, and “bulls” because their interest is to raise the market price. The broker's commission for buying or selling is $\frac{1}{4}$ of 1 per cent, except to members of the board, who pay \$2 per 100 shares. The business in “stock privileges,” as they are called, is a peculiar one, involving the technical terms “puts” and “calls.” A broker who sells a “put,” agrees to buy a specified stock in a certain number of shares, within a stated time, at a specified price, provided the seller be willing to deliver the stock at the price and time named. If the broker sells a “call,” he agrees to deliver a certain number of shares of a given stock on call within a stated time at a specified price. The cost of these privileges is arranged between the parties on the condition of the market, the time involved, etc. For the purpose of keeping up the gratuity fund for the heirs of deceased members of the exchange, every surviving member is assessed on occasion of a death in the sum of \$10. This system, which results in the payment of \$10,000 on the occasion of every death, was founded in 1873. If the net profits of the exchange exceed \$10,000, half the excess goes to the capital of the gratuity fund. The conduct of the business of the stock exchange is, as has already been remarked, under the strictest regulation, and the instances of dishonesty or impropriety have been, it is said, fewer in proportion to the number of persons engaged, and to the magnitude of the transactions involved, than in any other mercantile business. The stock exchange of New York is situated on Broad and New streets, and is a handsome building, containing probably the largest and strongest vaults for the reception of securities, in the world, and commodious rooms for the transaction of business. Visitors are admitted to a gallery set apart for the purpose.

STOCK-FISH, a commercial name of salted and dried cod and other fish of the same family, particularly the ling, hake, and torsk (see these heads). The fish is cured as soon as possible after being caught. It is split up from head to tail, cleansed from all particles of blood by plentiful washings with salt water; a piece of the back-bone is cut

away; and after the superfluous water has drained off, the fish are laid in long vats, covered with salt, and kept down by heavy weights. By and by they are taken out, washed and brushed, and then exposed to sun and air on a sandy beach or upon rocks. They are afterward gathered into little heaps, and when they assume a fine whitish appearance, known as the *bloom*, they are considered ready for the market. Great quantities of stock-fish are thus prepared in the northern parts of the world, and are not only used in the countries which produce them, but are largely exported to more southern regions, where they are in great demand. The cod, ling, and hake fishery of Scotland is next in importance to its herring-fishery. In 1873, according to the report of the Fishery commissioners, the yield was 160,716½ cwts. of dried fish, besides 12,381½ barrels cured in pickle. The quantity exported was 70,101½ cwts. cured dried. The quantity of stock-fish cured on the more southern coasts of Britain is inconsiderable.

STOCKHOLM, the capital of Sweden, is situated at the eastern extremity of the Maelar lake, in 59° 20' n. lat., and 18° 5' e. long. The pop. was, in '95, 271,638. Stockholm, which is one of the most beautiful capitals in Europe, is built partly on the continent, and partly on nine holms, or islands, lying in the channel through which the Maelar lake discharges its waters into the Baltic, about 36 m. distant. The Helgeandsholmen, Stadsholmen, and Riddarholmen, which formed the nucleus of the ancient city, founded in 1250 by Birgir Jarl, contain some of the finest public and private buildings, among which we may instance the royal palace, built in 1760, in the Italian renaissance style, and situated on a hill, commanding a view of the romantic shores of the lake. Near the palace, which possesses good antiquarian, numismatic, and other collections, a library, gallery of paintings, large gardens, etc., is the colossal statue of Gustavus III., on one of the fine quays which skirt the chief harbor of Stockholm; the cathedral, or St. Nicolaï's; the Knights' hall, with the adjoining market, ornamented with the fine statue of Gustavus Vasa, the council-house, the Riddarsholm kirke, where all the kings of Sweden since Charles X. have been buried, etc. Among the other public buildings, the most noteworthy are the observatory, the church of St. James, and the opera-house, with the neighboring and corresponding palace, in the aristocratic quarter of Norrmalm, which, with the new parade-ground, its public gardens, and its fine wide and even streets, ranks as the handsomest part of the town. The most picturesque of the nine islets of Stockholm is the Södermalm, on whose steep sides the houses, connected more frequently by steps than roads, rise in terraced rows to the even summit, which is crowned by St. Catherine's church. Numerous public gardens, summer palaces, and country-houses extend along the n.e. shores of the lake, and on the margins of Ladugårdslandet, now called Östermalm, the central portions of which present a picturesque blending of rocks, wooded heights, and romantic glens. On this side of Stockholm lies the famous Djurgård, or zoological gardens, one of the finest public parks in Europe, which occupies a peninsula two m. long, and one m. wide, whose natural beauties have been judiciously aided by art. The streets of the older quarters are narrow, crooked, and ill-paved; but in the better parts of the town there are fine straight streets and capacious squares and open places, with well-built stone houses; while in the suburbs the houses are mostly of wood. Stockholm is the seat of the government, and of the chief courts of law and administration, the residence of the sovereign, and the place of assembly for the legislative chambers. It is the center of the literary and social activity of the country, and has numerous scientific, artistic, educational, and benevolent institutions. In the immediate vicinity of Stockholm are the Karlsberg academy for naval and military cadets; and the Ulriksdal hospital, for invalided soldiers. No city has more picturesque environs, or more numerous public gardens and walks than Stockholm; while the many channels and canals connected with its large and commodious harbors facilitate traffic and intercommunication with the interior and with foreign ports. The docks have recently been greatly enlarged. Stockholm is the principal emporium of Swedish commerce; iron, timber, and deal planks are its main articles of export; but it is also the center of an active trade in the various manufactures of the place—as, for instance, leather, cotton, woolen, and silk fabrics, glass and porcelain, iron and steel goods, steam-engines, etc., which it sends, together with the ordinary colonial and other imports, to all the other towns of Sweden.

STOCKING-FRAME. The machine with which stockings, singlet drawers, and other similar garments are woven, was first invented by William Lee of Woodborough, Nottinghamshire. At first, it was a very simple affair, but has now become extremely complicated, although the simple principle upon which it was first originated is retained as the essential. This can only be understood by reference to the art of knitting, which originated it. In knitting, only one thread is used, and this formed into a succession of loops on a knitting-needle; each of these loops, then, has in succession another loop passed through it by means of another and similar needle, and this operation is carried on successively until the whole fabric is made. In the stocking-frame, instead of one needle to hold the stationary loops while those of the moving row are being inserted, there are as many needles as there are to be loops in the breadth of the web, and these are so made as to alternately form and give off the loops. Each needle terminates in a hook, a small indentation into which the bent point of the needle is easily pressed. The other end of the needle is fixed into a small casting of tin, formed to fit into a frame, and

be screwed tightly in, side by side with the rest of the needles. Between the needles are placed thin plates of lead or pewter, called *sinkers* in two rows; in one row, the sinkers move freely on an axis; in the other, they are all fixed to a bar, and move with it. The object of the loose ones, or *jack-sinkers*, is to make loops by pressing the thread down between the needles. The other row on the bar, or *lead-sinkers*, are brought down, so as to press simultaneously on the hooks of the needles, and press their points down into the little depression so that they will pass through the loops without catching one way, and take them up when opened and drawn in the contrary direction.

STOCKINGS. See **HOSIERY**.

STOCKMAR, CHRISTIAN FRIEDRICH, Baron, 1787-1863; b. Coburg; an army physician in 1814; in 1816 became physician to prince Leopold, who soon afterward made him his private secretary. In 1836 he brought about the marriage of prince Ferdinand of Coburg with queen Maria I. of Portugal, and in 1838 traveled with prince Albert to Italy. In 1858 he negotiated for the marriage of the present crown prince of Prussia with the English princess royal. See *Denkwürdigkeiten aus den Papieren des Freiherrn Christian Friedrich von Stockmar*, by Ernst von Stockmar (1872).

STOCKPORT, a t. of England, in the county of Chester, on the river Mersey, and 6½ m. s.e. of Manchester by railway. It is of great antiquity, but its prosperity is of modern date. Stockport has extensive manufactures of cottons, woolens, silks, machinery, brass and iron goods, shuttles, and brushes. Pop. '81, 59,544; '91, 70,253.

STOCKS, an apparatus of wood, much used in former times in England for the punishment of petty offenders. The culprit was placed on a bench, with his ankles fastened in holes under a movable board, and allowed to remain there for an hour or two. The period of their first introduction is uncertain, but in the second statute of laborers, 25 Edw. III. (1350), provision is made for applying the stocks to unruly artificers; and in 1376, the commons prayed Edward III. that stocks should be established in every village. Each parish had in later times its stocks, usually close to the churchyard, but sometimes in a more retired spot; and in some country places they are still to be seen, and not altogether disused. Combined with the stocks was often a whipping-post for the flagellation of vagrants. The use of stocks was general in the English North American colonies. In Massachusetts, a slanderer or profane person was first set in the stocks and then carried to the whipping-post. In the Southern states, slaves were sometimes set in the stocks as a punishment, as late as the present century.

STOCKS. See **DEBT, NATIONAL**; **STOCK-BROKER**; **STOCK EXCHANGE**.

STOCKTON, city and co. seat of San Joaquin co., Cal.; on Stockton channel, an estuary of the San Joaquin river, and on the Southern Pacific railroad; 45 m. s. of Sacramento. It was set off in 1849 by Charles M. Weber, the owner of a large Mexican grant, and was named in honor of Robert Field Stockton, of the U. S. navy, who took possession of California for the United States. In its early days it was the starting and outfitting point for miners bound for Calaveras, Tuolumne, and Mariposa cos. It is built on a plain in the great California valley; oak trees are scattered through its streets and surround its public buildings; and outside its limits are cultivable prairies extending for miles in all directions. It has an excellent harbor; the river here is navigable at all seasons by vessels of from 150 to 250 tons, and in the spring, above the city for 200 miles. It furnishes supplies to the farmers of the San Joaquin valley, receiving immense quantities of marketable produce, and is an important shipping point for wheat and wool. It contains the state insane asylum, a private sanitarium, the Hazelton public library, high school, public school library, national, state, and savings banks, electric light and street railroad plants, waterworks supplied chiefly from wells, St. Agnes's convent, St. Joseph's parochial school, and about a dozen churches. The city is the manufacturing center and the principal wheat market of the state. It has several large flour mills, grain warehouses, woolen mills, iron foundries, lumber and paper mills, machine shops, car works, agricultural implement works, and terra-cotta plant. There are daily, weekly, and monthly periodicals, several public squares filled with semi-tropical plants and flowers. The city has public school property valued at \$300,000, a total debt of less than \$325,000 and an assessed property valuation exceeding \$13,000,000. Pop. '90, 14,424.

STOCKTON, FRANCIS RICHARD, b. Philadelphia, 1834; was educated at the Central high school, Philadelphia; adopted literature as a profession, and became known first as a story-teller for young people, and then for both old and young; he became assist. ed. of *Scribner's Monthly* and *St. Nicholas*, but resigned, to work exclusively in preparing books. Besides a number of stories for children he has published: *Rudder Grange* (1879); *The Lady or the Tiger? and Other Stories* (1884); *The Casting Away of Mrs. Lecks and Mrs. Ale-shine*; *The Late Mrs. Null* (1886); *The Hundredth Man* (1887); *The Dusanter* (1888); *The House of Martha* (1891); *The Squirrel Inn*; *Fanciful Tales* (1894); *Adventures of Capt. Horn* (1895); *Mrs. Cliff's Yacht* (1896), and *The Great Stone of Sardis* (1897).

STOCKTON, RICHARD, 1730-81; b. N. J.; graduated at the college of New Jersey, then at Newark, 1748; admitted to the bar, 1754, where he soon became eminent; was in the executive council of New Jersey, 1768; judge of supreme court, 1774; in congress, 1776, where he cordially supported and signed the declaration of independence;

was on the committee to inspect the northern army and report its condition; after that service was taken prisoner by the British, confined in the common jail at New York, and treated with unusual severity, which exhausted his strength and cut short his life.

STOCKTON, ROBERT FIELD, 1795-1866; b. N. J.; became a midshipman while in college, 1810; was honorably mentioned in several actions, and made a lieutenant, 1814; distinguished himself in the war against Algiers; sent to the African coast, was influential in procuring the territory now known as the republic of Liberia, and captured several slave-ships; freed the West Indian seas from the pirates infesting them; engaged actively in politics, 1826-38; sent to the Mediterranean, 1838; made post-captain, 1839; gave plans for steam sloop of war *Princeton* which proved successful, marking an era in naval architecture; during the trial trip an unexplained explosion of the "big gun" wounded him and caused the death of the secretaries of war and the navy with three other distinguished men; commanded the Pacific squadron, 1845, and with a force of 1500 sailors and settlers, in 6 months conquered California and established a provisional government; resigned his commission, 1849, elected U.S. senator, 1851, and after promoting the abolition of flogging in the navy, resigned 1853. His *Life, Speeches, and Letters* was published 1856.

STOCKTON, THOMAS HEWLINGS, D.D., 1808-68; b. N. J.; studied medicine, became a Methodist Protestant minister; stationed at Baltimore, 1830; at Georgetown, 1833; chaplain to congress, 1833, holding the position for three successive sessions; chaplain to senate, 1862; resided in Philadelphia, 1838-47, and in Cincinnati, 1847-50; was pastor of St. John's Methodist Protestant church, Baltimore, 1850-55; pastor of the Independent church, Philadelphia, 1856-68. He published among others the following works: *Floating Flowers*; *The Bible Alliance*; *Stand up for Jesus, a Christian Ballad*; *Poems with Autobiographic and Other Notes*; *The Peerless Magnificence of the Word of God*. His vivid style and earnest pulpit delivery often drew great throngs.

STOCKTON-ON-TEES, a municipal borough and sea-port in the county of Durham, 11 m. e.n.e. of Darlington, on the left bank of the Tees. The broad and handsome High street is nearly a mile in length, and from it several minor streets diverge at right angles. A new t., known as South Stockton, has sprung up within the last few years on the right bank of the river, the two being connected by an iron bridge of three arches, built in 1887. The town contains two churches, a Roman Catholic chapel built by Pugin, several dissenting chapels, an athenæum, and other important edifices. The Stockton races, of some mark in the sporting world, are held here annually. Shipbuilding, chiefly in iron, is carried on to a great extent; and blast-furnaces, foundries, engine works, and extensive potteries and iron works are in operation. Sailcloth, ropes, linen, and diapers are manufactured; and there are breweries, corn mills, and spinning mills. The exports are chiefly iron manufactures, coal, coke, and agricultural produce; the imports are corn, timber in deals, spars, etc., and bark. The town is connected with the whole railway system of England and Scotland by the North-eastern railway company's branches, and there are two stations here. The Stockton and Darlington railway, the first in the united kingdom to commence passenger traffic, was opened for the double purpose of the conveyance of passengers and goods, Sept. 27, 1825. At Stockton the Tees is navigable for vessels of large tonnage; by a cut, by which a bend of the river is avoided, the town is brought 3 m. nearer the sea; the navigation of the river has been much improved, and great facilities for an extensive trade provided. Pop. of parl. borough, returning one member, '91, 68,895.

Stockton suffered severely from the incursions of the Scots in the early part of the 14th c., but even at that time it enjoyed considerable trade. It was taken for the parliament in 1644, and totally destroyed by the Roundheads in 1652. At the restoration it had become so poor a place that it contained only 120 houses, and most of these were built of clay.

STOCKWELL, STEPHEN N., 1823-81; b. Hardwick, Mass.; removed with his family to Worcester; at the age of 17 was apprenticed to the printer's trade. He passed a short time in St. John, New Brunswick, and with that exception lived continuously in Boston during a journalistic career of 40 years. He removed to Boston in 1842, entering the composing-room of the Boston *Journal*, became in time a reporter, afterward chief reporter. He was one of the corporators of the *Journal*, and his work was ceaseless in behalf of the interests of that paper, rising through intermediate positions to that of managing editor, and one of the proprietors, which position he resigned a few weeks previous to his death. He was a worker in Sunday-schools; and in his profession he was distinguished for strict business methods, and for his ability as an organizer, especially in the arrangement and condensation of daily news.

STODDARD, a co. in s.e. Missouri, having St. Francis river on the n.w.; intersected by the Missouri Southeastern and the St. Louis, Iron Mountain and Southern railroads; 840 sq.m.; pop. '90, 17,327, chiefly of American birth, with colored. It is drained by Castor river, lake Nicormy, 25 m. long and 4 m. wide, and small lakes and streams. The surface of the country was changed by an earthquake in 1811, and much of it is low and swampy. Forests of cypress grow near the lakes, and it has a good supply of building timber. The soil of the cultivable land produces good crops of grain, tobacco,

sorghum, and dairy products. Live stock find good pasturage. The manufactures are lumber and flour. Co. seat, Bloomfield.

STODDARD, AMOS, 1762-1813; b. Conn.; served in the revolutionary war, and at its close for some years practiced law in Maine, and was clerk of the Massachusetts supreme court. In 1798 he was made a capt. of artillery, and in 1804 was governor of the territory of Missouri. In the war of 1812 he was dangerously wounded at the siege of fort Meigs. He wrote *Sketches of Louisiana* (1810), and *The Political Crisis*, and a number of valuable historical papers.

STODDARD, DAVID TAPPAN, 1818-57; b. Mass.; graduated at Yale college, 1838; tutor in Marshall college, Penn.; declined a professorship at Marietta college, Ohio; studied theology at Andover; was tutor at Yale; licensed to preach by the Congregational association of Mass.; sailed as a missionary of the American board, 1843; had charge of the boys' seminary at Oroomiah, 1844; cholera prevailing and his health being impaired, he went to Erzeroom; visited the United States; returned to Persia, 1851. He prepared a *Grammar of Modern Syriac*; published in the *Journal of American Oriental Society*, 1855. *Observations of the Zodiacal Light* furnished sir John Herschel, and delivered a course of theological lectures in Syriac.

STODDARD, ELIZABETH (BARSTOW), b. Mass., 1823; married Richard Henry Stoddard in 1851, and has assisted him in editing several annuals. She has written three novels containing descriptions of life and scenery in New England; *The Morgesons* (1862); *Two Men* (1865); and *Temple House* (1867); also a juvenile, *Lolly Dink's Doings*.

STODDARD, RICHARD HENRY, born Mass., 1825; lost his father, who was a sea-captain, at an early age, and earned his living for several years in an iron-foundry in New York; printed privately in 1849 a volume of poems entitled *Footprints*, and a larger collection of *Poems* in 1852. He then received an appointment in the New York custom house, which he retained till 1870, devoting himself in the mean time to literary pursuits. He was city librarian in 1877, and he was from 1880 the literary critic of the *New York Evening Mail and Express*. He has published *Adventures in Fairy Land* (1853); *Songs of Summer* (1857); *Town and Country* and the *Voices in the Shells* (1857); *Life, Travels, and Books of A. von Humboldt* (1860); *The King's Bell*, a poem (1862); *The Story of Little Red Riding Hood*, in verse (1864); *The Children in the Wood*, in verse (1865); *Putnam the Brave* (1869); *The Book of the East* (1871); an edition of his *Poems* (1880); and *The Lion's Cub, and Other Poems* (1890). Stoddard has edited among other books, *Gen. Lyon's Political Essays, with his Life* (1861); *The Loves and Heroines of the Poets* (1861); *J. G. Vassar's Twenty-one Years round the World* (1862); *Melodies and Madrigals, mostly from old English Poets* (1865); *The Late English Poets* (1865); *Poets and Poetry of America* (1872); *Female Poets of America* (1874); the *Bric-a-Brac Series* (1874 et seq.), and *Under the Evening Lamp* (1892).

STODDARD, SOLOMON, 1643-1729; b. Boston; graduated at Harvard college, 1662; was fellow and librarian of the college, 1667-74; ordained minister of First church, Northampton, 1672. He was a learned man and an acute disputant. Believing the Lord's Supper to be a converting ordinance, he maintained that all baptized persons of correct moral life, though unconverted, might lawfully partake of it. He published in 1700 *The Doctrine of Instituted Churches* in reply to the work of Increase Mather entitled *The Order of the Gospel*; also *A Guide to Christ*; a treatise concerning *Conscience*; *The Trial of Assurance*. His views as to the Lord's Supper were quite different from those usual in Puritan churches, and did not gain permanence among them.

STODDERT, BENJAMIN, 1751-1813, b. Md.; served as capt. and maj. in the American revolutionary army, and distinguished himself at Brandywine. He was secretary of the navy, 1798-1801, and afterwards a successful merchant.

STOEVEER, MARTIN LUTHER, PH.D., LL.D., 1820-70; b. Penn.; graduated at university of Pennsylvania, 1838; tutor, principal of the primary department, and professor of Latin there, 1839-70. He published *Self-Culture*; *Life of H. M. Muhlenburg*; *Memorial of P. F. Mayer*; *Brief Sketch of the Lutheran Church in the U. S.*; edited *Literary Record*, 1847-48; *Evangelical Review*, 1857-70.

STOICS, the name for the sect of ancient moralists opposed to the Epicureans in their views of human life. The Stoical system dates from the end of the 4th c. B.C.; it was derived from the system of the Cynics, whose founder, Antisthenes, was a disciple of Socrates. Indeed, the doctrines, but still more the manner of life, and most of all the death, of Socrates, were the chief foundations of the Stoical philosophy.

The founder of the system was ZENO, from Cittium in Cyprus (he lived from 340-260 B.C.), who derived his first impulse from Crates the Cynic. He opened his school in a building or porch, called the *Stoa Pacile* ("painted porch") at Athens, whence the origin of the name of the sect. Zeno had for his disciple CLEANTHES, from Assos in the Troad (300-220 B.C.), whose *Hymn to Jupiter* is the only fragment of any length that has come down to us from the early Stoics, and is a remarkable production, setting forth the unity of God, his omnipotence, and his moral government. CHRYSIPPUS, from Soli in Cilicia (280-207 B.C.), followed Cleanthes, and, in his voluminous writings, both defended and modified the Stoical creed. These three represent the first period of the system. The second period (200-50 B.C.) embraces its general promulgation, and its introduction to the Romans. Chrysippus was succeeded by ZENO of Sidon, and DIOGENES of Babylon;

then followed ANTIPATER of Tarsus, who taught PANÆTIUS of Rhodes (died 112 B.C.), who, again, taught POSIDONIUS of Apamea, in Syria. (Two philosophers are mentioned from the native province of St. Paul, besides Chrysippus—Athenodorus, from Cana in Cilicia; and Archedemus, from Tarsus, the apostle's birthplace. It is remarked by sir A. Grant, that almost all the first Stoics were of Asiatic birth; and the system itself is undeniably more akin to the oriental mind than to the Greek.) Posidonius was acquainted with Marius and Pompey, and taught Cicero; but the moral treatise of Cicero, *De Officiis*, is derived from a work of Panætius. The third period of Stoicism is Roman. In this period we have Cato the younger, who invited to his house the philosopher Athenodorus; and, under the empire, the three Stoic philosophers whose writings have come down to us—SENECA (6 B.C.—65 A.D.), EPICTETUS (60–140 A.D.), who began life as a slave, and the emperor MARCUS AURELIUS ANTONINUS (121–180 A.D.). Stoicism prevailed widely in the Roman world, although not to the exclusion of Epicurean views.

The leading Stoical doctrines are given in certain phrases or expressions, as “life according to nature,” the ideal “wise man,” “apathy” or equanimity of mind, the power of the “will,” the worship of “duty,” the constant “advance” in virtue, etc. But perspicuity will be best gained by considering the *moral* system under four heads—the theology; the psychology or theory of mind; the theory of the good or human happiness; and the scheme of virtue or duty.

I. Their theological doctrines comprehended their system of the universe, and of man's position in it. They held that the universe is governed by one good and wise God, together with inferior or subordinate deities. God exercises a moral government; under it the good are happy, while misfortunes happen to the wicked. According to Epictetus, God is the father of men; Antonius exults in the beautiful arrangement of all things. They did not admit that the Deity intermeddled in the smaller minutiae; they allowed that omens and oracles might be accepted as signs of the foreordained arrangement of God. They held this foreordination even to the length of fatalism, and made the same replies as have been given in modern times, to the difficulty of reconciling it with free will, which in their system was unusually prominent. As to the existence of evil, they offered explanations such as the following: God is the author of all things except wickedness; the very nature of good supposes its contrast evil, and the two are inseparable, like light and dark, which may be called the argument from relativity; in the enormous extent of the universe, some things must be neglected; when evil happens to the good, it is not as a punishment, but as connected with a different dispensation; parts of the world may be presided over by evil demons; what we call evil may not be evil.

Like most other ancient schools, the Stoics held God to be corporeal like man; body is the only substance; nothing incorporeal could act on what is corporeal; the first cause of all, God or Zeus, is the primeval fire, emanating from which is the soul of man in the form of a warm ether.

It is for human beings to recognize the universe as governed by universal law, and not only to raise their minds to the comprehension of it, but to enter into the views of the Creator, who must regard all interests equally; we are to be, as it were, in league with him, to merge self in the universal order, to think only of that, and its welfare. As two is greater than one, the interests of the whole world are infinitely greater than the interests of any single being, and no one should be satisfied with a regard to anything less than the whole. By this elevation of view we are necessarily raised far above the consideration of the petty events befalling ourselves. The grand effort of human reason is thus to rise to the abstraction or totality of entire nature; “No ethical subject,” says Chrysippus, “could be rightly approached except from the preconsideration of entire nature, and the ordering of the whole.”

As to immortality, the Stoics precluded themselves, by holding the theory of the *absorption* of the individual soul at death into the divine essence; but, on the other hand, their doctrine of advance and aspiration is what has in all times been the main natural argument for the immortality of the soul. For the most part, they kept themselves undecided as to this great doctrine, giving it as an alternative, reasoning as to our conduct on either supposition, and submitting to the pleasure of God in this as in all other things.

In arguing for the existence of divine power and government, they employed what has been called the argument from design, which is as old as Socrates. Man is conscious that he is in himself an intellectual or spiritual power, from which, by analogy, he is led to believe that a greater power pervades the universe, as intellect pervades humanity.

II. Next, as to the constitution of the mind. We have bodies like animals, but reason or intelligence, like the gods. Animals have instinctive principles of action; man alone has a rational intelligent soul. According to Antoninus, we come into contact with Deity by our intellectual part, and our highest life is thus the divine life.

But the most important Stoical doctrine respecting the nature of man is the recognition of reason as a superior power or faculty that subordinates all the rest—the governing intelligence. (Very nearly the same phraseology is used by bishop Butler in setting forth the supremacy of conscience.) This, however, is not a mere intellectual principle, but an active force, uniting intellect and will. The bodily sensibilities are opposed to this higher reason and will, which, however, is strong enough to control them. Another way of expressing the same view was the power of the mind over the body, which was

dwelt upon by Epictetus in the most exaggerated form. The introduction of so glaring a mistake as that sickness may affect the body without enfeebling the mind could only end in practical failures, or else in contradiction.

In order to maintain their contrast with the Epicureans, the Stoics said that pleasure and pain are not principles of nature; by which they must have meant that humanity is not in fact, at least exclusively, governed by these, and that, in the regenerated man, they are not governing principles at all. Now, it is true, and a truth important for many practical purposes, that we are sometimes impelled to action without reference to our pleasures and pains; our habits often exemplify this state; it is still better shown in what are called "fixed ideas," as in involuntary imitation and sympathy. But these are exceptions; and any system that sets itself against the main fact that pleasure and pain are the great moving forces of mankind must somewhere or other contradict itself.

In Seneca we find something very closely approaching to the Christian doctrine of the corruption of human nature. The littleness of humanity was a favorite theme of Antoninus, and naturally followed from the Stoical mode of contemplating the universe at large.

The doctrine called the freedom of will may be said to have originated with the Stoics, although with them it was chiefly a rhetorical mode of expressing the dignity of the wise man, and his power of rising superior to circumstances.

To prepare the way for the Stoical precepts, Epictetus distinguished between things in our power and things not in our power. The things in our power are our opinions and notions about objects, and all our affections, desires, and aversions; the things not in our power are our bodies, wealth, honor, rank, authority, etc., and their opposites. The application is this: wealth and high rank may not be in our power, but we have the power to form an *idea* of these—namely, that they are unimportant, whence the want of them will not grieve us. A still more pointed application is to death, whose force is entirely in the idea.

III. We must consider next the Stoical theory of happiness, or rather of the good, which with them was not identified with happiness. They began by asserting that happiness is not necessary, and may be dispensed with, and that pain is no evil, which, however, if followed consistently, would dispense with all morality and all human endeavor. Substantially and practically, they held that pains are an evil, but, by a proper discipline, may be triumphed over. They disallowed the direct and ostensible pursuit of pleasure as an end (the point of view of Epicurus), but allured their followers partly by promising them the victory over pain, and partly by certain enjoyments of an elevated cast that grew out of their plan of life.

Pain of every kind, whether from the casualties of existence, or from the severity of the Stoical virtues, was to be met by a discipline of endurance, a hardening process, which, if persisted in, would succeed in reducing the mind to a state of apathy or indifference. A great many reflections were suggested in aid of this education. The influence of exercise and repetition in adapting the system to any new function, was illustrated by the Olympian combatants, and by the Lacedæmonian youth who endured scourging without complaint. Great stress was laid on the instability of pleasure, and the constant liability to accidents; whence we should always be anticipating and adapting ourselves to the worst that could happen, so as never to be in a state where anything could ruffle the mind. It was pointed out how much might still be made of the worst circumstances—poverty, banishment, public odium, sickness, old age—and every consideration was advanced that could "arm the obdurate breast with stubborn patience, as with triple steel."

It has often been remarked that such a discipline of endurance was peculiarly suited to the unsettled condition of the world at the time, when any man, besides the ordinary evils of life, might in a moment be sent into exile, or sold into slavery. Moreover, it is a discipline adapted to a certain class of dispositions existing in all ages—the men that prefer above all things "equanimity" of mind, and would rather dispense with great occasional pleasures than risk their state of habitual composure.

Next to the discipline of endurance, we must rank the complacent sentiment of pride, which the Stoic might justly feel in his conquest of himself, and in his lofty independence and superiority to the casualties of life. The pride of the Cynic, the Stoic's predecessor, was prominent and offensive, showing itself in scurrility and contempt toward everybody else; the Stoical pride was a refinement upon this, but was still a grateful sentiment of superiority, which helped to make up for the surrender of indulgencies. It was usual to bestow the most extravagant laudation on the "wise man," and every Stoic could take this home to the extent that he considered himself as approaching that great ideal.

The last and most elevated form of Stoical happiness was the satisfaction of contemplating the universe and God. Epictetus says that we can discern the providence that rules the world, if we possess two things—the power of seeing all that happens with respect to each thing, and a grateful disposition. The work of Antoninus is full of studies of nature in the devout spirit of "passing from nature to nature's God;" he is never weary of expressing his thorough contentment with the course of natural events, and his sense of the beauties and fitness of everything. Old age has its grace, and

death is the becoming termination. This high strain of exulting contemplation reconciled him to that complete submission to whatever might befall, which was the essential feature of the "life according to nature."

IV. The Stoical theory of virtue is implicated in their ideas of the good, now described.

The fountain of all virtue is manifestly the life according to nature, as being the life of subordination of self to more general interests—to family, country, mankind, the whole universe. If a man is prepared to consider himself absolutely nothing in comparison with the universal interest, and to regard it as the sole end of life, he has embraced an ideal of virtue of the loftiest order. Accordingly, the Stoics were the first to preach what is called "Cosmopolitanism;" for although, in their reference to the good of the whole, they confounded together sentiment, life, and inanimate objects—rocks, plants, etc., solicitude for which was misspent labor—yet they were thus enabled to reach the conception of the universal brotherhood of mankind, and could not but include in their regards the brute creation. They said: "There is no difference between Greeks and barbarians; the world is our city." Seneca urges kindness to slaves, for "are they not men like ourselves, breathing the same air, living and dying like ourselves?"

The Epicureans declined, as much as possible, interference in public affairs, but the Stoical philosophers all urged men to the duties of active citizenship. Although there had been many good and noble men among the pagans, yet positive beneficence had not been preached as a virtue before the Stoics. They adopted the four cardinal virtues (wisdom, or the knowledge of good and evil; justice; fortitude; temperance) as part of their plan of the virtuous life, the life according to nature. Justice, as the social virtue, was placed above all the rest. But most interesting to us are the indications of the idea of beneficence. Epictetus is earnest in his exhortations to forgiveness of injuries. Antoninus often enforces the same virtue, and suggests considerations in aid of the practice of it; he contends as strongly as Butler and Hume for the existence of a principle of pure, that is, unselfish, benevolence in the mind—in other words, that we are made to advance each other's happiness.

There is also in the Stoical system a recognition of duties to God, and of morality as based on piety. Not only are we all brethren, but also the "children of one Father."

The extraordinary stress put upon human nature by the full Stoic ideal of submerging self in the larger interests of being, led to various compromises. The rigid following out of the ideal issued in one of the paradoxes, namely, that all the actions of the wise man are equally perfect, and that, short of the standard of perfection, all faults and vices are equal; that, for example, the man that killed a cock without good reason was as guilty as he that killed his father. This has a meaning only when we draw a line between spirituality and morality, and treat the last as worthless in comparison of the first. The later Stoics, however, in their exhortations to special branches of duty, gave a positive value to practical virtue, irrespective of the ideal.

The idea of duty was of Stoical origin, fostered and developed by the Roman spirit and legislation. The early Stoics had two different words for the "suitable" (*kathēkon*) and the "right" (*katorthōma*); although it is a significant circumstance that the "suitable" is the lineal ancestor of our word "duty" (through the Latin *officium*).

It was a great point with the Stoic to be conscious of "advance," or improvement. By self-examination, he kept himself constantly acquainted with his moral state, and it was both his duty and his satisfaction to be approaching to the ideal of the perfect man. When renouncing the position of "wise," he yet claimed to be advancing. This idea, familiar to the modern world, was unknown to the ancients before the Stoics. It is very illustrative of the unguarded points and contradictions of Stoicism, that contentment and apathy were not to permit grief even for the loss of friends. Seneca, on one occasion, admits that he was betrayed by human weakness on this point. On strict Stoical principles, we ought to treat the afflictions and the death of others with the same frigid indifference as our own; for why should a man feel for a second person *more* than he ought to feel for himself, as a mere unit in the infinitude of the universe? This is the contradiction inseparable from any system that begins by abjuring happiness as the end of life. We may be allowed to regard our own happiness as of no importance, but if we apply the same measure to happiness in general, we are bereft of all motives to benevolence; and virtue, instead of being set on a loftier pinnacle, is left without any foundation.

The Stoical system has largely tintured modern ages, in spite of its severity. It has always had a charm as an ideal, even when men were conscious of not realizing it. It may be still considered as a grand experiment in the art of living, from which valuable lessons have resulted; just as a believer in alchemy, or in the perpetual motion, might make useful experimental discoveries. The limitation of wants, the practice of contentment, the striving after equanimity, the hardening of one's self against the blows of fortune, are all familiar to the moralist of later ages. A qualified form of the subordination of self to the general welfare, belongs to the modern theories of virtue.

The chief ancient authorities on the Stoics are the writings of Epictetus, Marcus Antoninus, and Seneca, themselves Stoical philosophers, together with notices occurring in Cicero, Plutarch, Sextus Empiricus, Diogenes Laërtius, and Stobæus. The completest

modern account of the system occurs in Zeller's *Philosophie der Griechen*, vol. iii. See also an article by sir Alexander Grant in the *Oxford Essays* for 1858; and *Stoicism*, by Capes, 1880.

STOKES, a co. in n. North Carolina, adjoining Virginia, drained by the Dan river, about 510 sq.m.; pop. '90, 17,199, inclu. colored. The surface is hilly and heavily timbered. The soil is fertile. The principal productions are corn, wheat, rye, and tobacco. Co. seat, Danbury.

STOKES, Sir GEORGE GABRIEL, one of the greatest living mathematicians and natural philosophers in Europe, was born, in 1819, at Skreen, co. Sligo, Ireland; educated at the school of Rev. R. H. Wall, D.D., Dublin; afterward at the Bristol college. He entered Pembroke college, Cambridge, in 1837; graduated in 1841, as senior wrangler, and first Smith's prizeman; became fellow of Pembroke in the same year; and was elected, in 1849, to fill, as one of the worthiest of Newton's successors, the Lucasian chair of mathematics in Cambridge. In 1885 he was appointed president of the Royal society.

He is best known, popularly, by his beautiful discovery of fluorescence (see PHOSPHORESCENCE). His paper *On the Change of the Refrangibility of Light*, is printed in the *Philosophical Transactions* for 1852-1853. His recent important physiological application of optical methods to the study of the oxidation of the blood, is noticed under SPECTRUM. But to mathematicians and natural philosophers, Stokes is known by a number of admirable papers in the *Cambridge Philosophical Transactions*, the *Cambridge and Dublin Mathematical Journal*, and the *Philosophical Magazine*. In them he has greatly extended and improved the mathematical treatment of questions connected with the distortion of elastic solids, the motion of waves in water, the undulatory theory of light, the summation of series, the internal friction of fluids, etc. Another excellent work by Stokes is his *Report on Double Refraction*, published in the British association reports for 1862. He was president of the British association in 1869. He has also published *Lectures on Solar Physics*, the *Burnet Lectures on Light* (1884), *Mathematical and Physical Papers* (1880-83), and *Gifford Lectures on Natural Theology* (1891-3). He was made a baronet in 1885.

STOKE-UPON-TRENT, a parliamentary borough and manufacturing t. of Staffordshire, 145 m. from London by the London and North-western railroad. It is the center of the "district" of Stoke, familiarly named the "Potteries," and is connected with Burslem and other places by steam tramways. The town of Stoke is regularly built, and contains many modern houses. The principal public buildings are the town-hall, New Market hall, and Minton Memorial building. There is also a statue to Josiah Wedgwood. Stoke owes its importance primarily to its porcelain and earthenware manufactures. The earthenware manufactures of the parish of Stoke are carried on in about 200 factories. In the vicinity are numerous coal-mines. Pop. of parl. borough, which sends one member to the house of commons, 1891, 75,352.

STOLBERG, CHRISTIAN, Count of, a German poet, b. at Hamburg, Oct. 15, 1748. He belonged to one of the oldest German families, originally of Thuringia, and which is mentioned in authentic documents of the 11th century. Stolberg studied at Göttingen from 1769 to 1774, where he was one of a distinguished literary circle in n. Germany, embracing Boje, Bürger, Miller, Voss, Hölty, and Leisewitz. In 1777 he married Louise, countess of Reventlow, whom he had previously celebrated in his verses; and after 1800, lived apart from public life on his estate of Windeby, near Eckernförde in Slesvig, where he died Jan. 18, 1821. As a poet, he was inferior in genius to his younger brother, but his pictures of family life are very fine. His principal works are *Gedichte* (Leip. 1779); *Gedichte aus dem Griechischen* (Hamb. 1782); *Schauspiele mit Chören* (Leip. 1787); and *Vaterländische Gedichte* (along with his brother; Hamb. 1815).

STOLBERG, FRIEDRICH-LEOPOLD, Count of, younger brother of the preceding, was b. at Bramstedt, Nov. 7, 1750, studied at Halle and Göttingen, and after a visit to Switzerland and Italy, in the course of which he made the acquaintance of Goethe at Frankfurt, and of Lavater at Zürich, he became in 1777 minister-plenipotentiary of the episcopal prince of Lübeck at the court of Denmark. Stolberg filled various other official situations in the course of his public life; but becoming a convert to Roman Catholicism, he resigned all his employments, and henceforth lived mainly in the society of his co-religionists. The causes that led him to take a step which lost him many old and dear friends, were partly the theological strifes between the Rationalists and orthodox Lutherans in Holstein—the country where he mostly resided, and partly his study of the controversial works of the Catholic writers during a second visit to Italy in 1790-91. He died at Sondermühlen, near Osnabrück, Dec. 5, 1819. Stolberg is a superior poet to his elder brother. There is greater boldness in his ideas and imagery, and he displayed a wonderful facility in versification. We have from him specimens of all sorts of poetry, songs, odes, elegies, metrical romances, satires, descriptive verse, and dramas, which are contained in the *Werke der Brüder Stolberg* (22 vols., Hamb. 1820-25). See *Friedr.-Leopold, Graf zu Stolberg*, by Nicolovius (Mainz, 1846). A very good account of Stolberg's change of faith, and of that literary circle of n. Germany in which he moved until his conversion, will be found in a book called *Entiner Skizzen* (Sketches of Entin), by Wilhelm von Bippin (Weimar, 1862).

STOLE (Gr. *stolé*, Lat. *stōla*, a robe) is the name of one of the sacred vestments used in the Latin church, and with some modification, in the Greek church also. It originated in a wide and flowing robe of linen, called also *orarium*, which hung from the shoulder, and which had a narrow embroidered border of a different color, as we learn

from St. Ambrose's sermon on the death of Satyrus (n. 43), and from Jerome's letter to Nepotianus (Ep. 52). The present stole seems to be the traditional representative of the embroidered border of the orarium in the Roman Catholic church, and consists of a narrow band of silk or precious stuff, edged and fringed with gold or embroidery. It is worn over the shoulders by priests and deacons, but in a different fashion—the former wearing it over both shoulders, with the ends hanging in front, or crossed upon the breast; the latter carrying it only from the left shoulder to the right side, where the pendent ends are fastened. In the eastern church the stole is worn pendent, over both shoulders by priests, over the left shoulder only by deacons. The stole is worn at mass, and in the administration of sacraments, in certain blessings, and in more solemn forms of preaching. It is also used, in some cases, as a symbol of jurisdiction, in which sense it is constantly worn by the pope, even when not officiating; and there is a very remarkable usage in Italy and other Catholic countries, illustrative of the same principle as to jurisdiction, of the parish priest, after he has administered extreme unction to a sick person, *leaving the stole upon the foot of the bed, not to be withdrawn until the death or recovery of the invalid.* Like the other sacerdotal vestments, the stole must be blessed by a bishop, or a priest delegated by a bishop. In the English church the stole is now generally used by the clergy, and is worn with the same difference by priests and deacons. In the case of dignitaries, doctors, and chaplains of noblemen or bishops, it is worn in the form of a scarf. The use of the stole in the English church appears to rest only upon ancient custom, as it is not specified in any rubric or canon. It is usually of black silk, fringed at the ends, with sometimes crosses embroidered.

STOLEN GOODS, in point of law, stand in this situation in England: a *bonâ fide* purchaser of such goods, who has not bought them in market overt, is bound to restore them to the true owner; but if the goods are sold in market overt, the purchaser is entitled to keep them, unless the owner has duly prosecuted and convicted the thief. Market overt means the open market in towns and places where a legal market is held, and the old doctrine was, that as all sales were conducted by exposure of goods in an open place, the owner of the lost goods was likely to find them easily by going to the nearest market—a doctrine which is now quite inapplicable to modern habits. In the city of London, every shop is held to be a market overt within the above rule, but this only applies to the city proper, and not the suburbs and western parts of the metropolis. The above rule, as to stolen goods, does not apply to valuable securities which are stolen, if the security has been paid or discharged *bonâ fide* by the person liable, or if the security is a negotiable instrument, and it have been *bonâ fide* transferred or delivered for a just and valuable consideration, without any notice, and without any reasonable cause to suspect that the same had been obtained by felony or misdemeanor. The law is obviously harsh as regards owners, for a man who has had the misfortune to have his goods stolen, must go to the further loss and expense of prosecuting the thief before he can recover them. There are no markets overt in the U. S. Any person buying stolen goods gets no better title to them than the thief had, i.e., the original owner may take them anywhere that he may find them. The rule is subject to the qualification that money or negotiable instruments, as coupon bonds, checks to bearer, bank bills, etc., which are intended to pass from hand to hand in the ordinary transactions of business may become the property of a purchaser from the thief in good faith. The reason of this distinction is obvious. Were the rule otherwise there would be an incalculable and undiscoverable risk attending every business transaction, so that commercial relations would be hampered and harmed.

STOLP, a garrisoned t. of Prussia, chief town of a circle in the province of Pommern, is situated on the river Stolpe, 12 m. from its mouth, and 75 m. w. of Danzig. Stolp, which is composed of an old and new town, with four suburbs, has a castle, 4 churches (one of which, the *Marienkirche*, dates from the 14th century), a hospital for invalids, amber and other manufactures, and an active general trade. Pop. '95 (with garrison), 24,845.—At the mouth of the river, lies Stolpmünde (pop. '95, about 2000).

STOMACH. The anatomy and physiology of the human stomach is fully treated in the article **DIGESTION**. This organ, the most important for the preparation of the nutriment of the body, varies greatly in different animals. Some of the protozoa, as infusoria, may be said to be all stomach, as they are, some of them, nothing but contractile sacs for the reception of alimentary matter which is contained in the water they inhabit. Another view may be taken, which is that these very low animals have no stomachs, and that all the digestion they perform is a tissue assimilation of organic and mineral matter. They are, however, generally spoken of as having stomachs. In the cœlenterata there is considerable diversity in the structure and relations of the stomach to the other parts, and yet a remarkable unity of plan, which is held by some to be evidence of progressive development; but the existence of a plan having perfect analogies may not be regarded as more than the evidence of order; and this is as consistent with the belief that an organism commenced its zoological life in much the same condition in which we find it, as with the hypothesis that it has been the subject of a constant change of type. In the hydrozoa the stomach cavity and body cavity are one. In actinozoa, that which answers to the stomach is a wide tube which empties into the body cavity; but the body cavity acts as a stomach also; and in fact what is usually regarded as a stomach is probably no more than an œsophagus or gullet. There is

a tendency in actinozoa to the formation of special organs, which means that there is more specialization of organs. In the *echinodermata*, the sub-kingdom which includes the sea-urchins, star-fishes, etc., there is a higher organization generally, as is seen in the radiate nervous system, and in these animals we find a stomach and an intestinal canal having no communication with the body cavity. In the star-fishes the stomach occupies the whole central part of the body. From it two long, tapering, ramified cæca are given, off opposite the commencement of each ray, and are distributed through it in a central line, so that there are ten pairs of cæcal appendages. In addition to these the stomach is provided with small, short cæca between the large trunks in the rays. In the sub-kingdom annulosa the form of the digestive apparatus exhibits much variety. In some orders, as *tanaida*, comprising the tape-worms, there is no stomach, nor even mouth proper. In the order *trematoda* there is a mouth and an alimentary canal, and consequently an arrangement which answers for a stomach, but there is only one aperture for the entrance of food and expulsion of fæces. In the second division of annulosa, viz., in *nematelmia*, there are in the first order *acanthocephala*, internal parasites without mouth or alimentary canal, but with proboscis and suctorial apparatus. In the next order *gordiacea*, comprising animals which during a portion of their existence are parasitic insects, there is sometimes an imperfectly developed digestive apparatus, or none. In the next order, *nematoda*, including the lumbricoid worms which infest the alimentary canal of mammals, there are well-developed digestive organs suspended freely in a body cavity, and provided with a mouth and excretory orifice. In the sub-class rotifera (wheel animalcules) there is a complex organization with a ganglionic nervous system. The stomach is large and well developed, but there are no organs of blood circulation or of respiration, although there is a corpusculated fluid in the body cavity. Among the annelides the common leech has an extensive digestive apparatus, the stomach not only being large and running nearly the whole length of the body, but provided with eleven capacious cæca.

In the crustaceans, particularly the lobster, the digestive organs are elaborate. The apparatus for mastication is efficient, and the mouth opens by a very short narrow gullet into a capacious stomach in which there are a great number of very minute teeth, and in addition three very large calcareous teeth situated near the pyloric orifice. A number of strong, calcareous bones, longitudinal in direction, support the membranous portion of the stomach, and form a basis for the support of the large teeth. The entire organ is covered externally with a layer of muscles of great power. Two of the large teeth resemble the molars of an elephant, and they have a sort of rotary molar motion. Between them is the third large tooth, which has a rounded surface, and assists in mastication by constantly pushing the food between the molars. The whole of this apparatus is called "the lady in the lobster." Some insects have even more elaborate stomachs than crustaceans. The locust has a marvelous masticating and digesting organism. See LOCUST and GRASSHOPPER, under sub-title *General Anatomy*. They seem to be furnished with all possible accessories for the trituration and solution of the coarse food upon which they live. The coleoptera are, as an order, perhaps possessed of more powerful digestive apparatus than the orthoptera, some of the beetles almost equaling the acrididae. They have a crop, a gizzard, and a chylic stomach, and are enormous eaters, as every housekeeper knows who has had experience with croton bugs and cockroaches, and every farmer who has defended his potato crop against the ravages of the Colorado beetle. (See POTATO BUG.) The crop and stomach of the honey-bee is a marvelous piece of mechanism. The œsophagus dilates into a large crop, the honey-collecting bag, which is capable of being dilated by muscular action so as to exhaust the nectar from flowers. The true stomach is connected with the crop in a remarkable manner. It commences by a small tube, which can be inserted into the crop or withdrawn from it. When inserted it is doubled upon itself, forming a shut valve through which the honey cannot pass. The bee feeds itself at will by withdrawing the tubular portion of the true stomach, when the contents of the crop are permitted to pass into it. In the mollusca the stomach and alimentary canal are often simple in structure, but efficient; for digestive fluids are furnished in great abundance. The rapid growth of the oyster is evidence of its power of digestion and assimilation. In some of the gasteropod mollusks the stomach is more complex, being often provided with cartilaginous or calcareous plates for the trituration of food. Distinct salivary glands are usually present, and the liver is well developed. The cephalopod mollusks, as the cuttle fishes and octopus, have enormously efficient digestive apparatus. See CEPHALOPODA.

In fishes the stomach is usually long and tapering, but the whole alimentary canal is frequently shorter than the fish. Their food is chiefly animal, and easy of digestion. In the batrachians we first meet with a structure of the mucous coat of the stomach bearing a resemblance to that of mammals. The stomach of the toad has gastric follicles which secrete a gastric fluid having properties like that secreted by the stomachs of higher animals, and the intestines present a beautiful arrangement of the capillary blood vessels. The ophidian reptiles have large and distensible stomachs for the reception of their prey, but their digestion is sluggish. In the chelonians there is a great advance. The gastric cells are large, and are freely traversed by capillary blood-vessels. In birds there is considerable variety in the form and extent of the stomach and alimentary canal,

depending upon their habits. See BIRDS. In mammals there is more variety than in birds, as their structure and habits are more variable. Carnivorous animals require a much less complicated digesting apparatus than omnivorous or herbivorous. See RUMINANTIA. The great ant-eater has, however, an apparatus in many respects resembling that of a common fowl, while the blood-sucking bat (*desmodus*) has a stomach whose capacity has more relations to its office of receiver than of digester, the pyloric end, where digestion is performed in this case, being very small, but sufficient for the disposal of the easily digested food. The cardiac portion is enormously elongated above the entrance of œsophagus, forming an elongated cæcum in contact at its further end with the spleen. There is considerable variety in the digestive apparatus of the quadrumana. The *semnopithecus entellus*, or sacred monkey of India, has an enormous stomach. A full-grown female of this species, examined by Prof. Owen, had a stomach which, when distended and dried, measured 2 ft. 7 in. along the greater curvature, and 1 ft. along the lesser. Its greatest circumference was 1 ft., and its least, about 2 in. above the pyloric orifice, was $3\frac{3}{4}$ in. Prof. Owen says that it may be regarded as consisting of three divisions: a cardiac pouch, a middle, sacculated portion, and a narrow, elongated canal, sacculated at its commencement and simple near its termination, which portion he considers to be the digesting portion of the organ. In the genus *cercopithecus*, which was formerly ranked with *semnopithecus*, the stomach has the usual simple construction, resembling that of most quadrumana and of man. It is generally thought that this enlarged stomach is not because of the vegetable-eating habits of the entellus, but as an offset to its want of cheek pouches, which other monkeys have, for the purpose of temporarily stowing away food.

STOMACH, DISEASES OF. In the discussion of the diseases of any organ, it is customary to begin with the consideration of its inflammation. In the stomach, however, acute *gastritis*, or inflammation of the mucous membrane of that organ, is so rare a disease, except as a result of the administration of an irritant poison, that it might almost pass unnoticed. Thus Louis states that during six years' experience at La Charité (one of the leading Parisian hospitals), in which he made notes of 6,000 cases of disease, and 500 dissections, he did not meet with a single case of fatal idiopathic (or spontaneous) gastritis. The simple fact, however, that this disease is almost always the result of poison, gives it a special interest, and renders it especially necessary that the physician should be so thoroughly acquainted with its symptoms, as to be able with certainty to detect it, and thus to be led to investigate its cause.

The symptoms which indicate that an irritant poison has been received into the stomach, are a gradually increasing sensation of uneasiness or heat, which shortly assumes an acute burning character in the epigastric region. This pain is accompanied with vomiting, which becomes increasingly frequent as the pain augments, and often with hiccup. There is usually extreme tenderness on pressure, and the patient bends his body forward to relax the muscular tension. During the accession of these symptoms, there is a marked degree of excitement, as indicated by the acceleration of the pulse and breathing, and the heat of the skin. This condition is, however, soon exchanged for one of prostration. The skin becomes cold and clammy, the pulse thready and feeble, and the breathing catching and intermittent; until finally, after a variable period of exhaustion, the patient sinks, usually retaining his mental faculties to the last. Although the above-described symptoms are always more or less present, each irritant poison occasions some special symptom, and some characteristic lesion; and the period at which death ensues varies for different poisons. Hence, quite apart from the results of analysis, a fair conjecture can usually be made as to the individual poison which has been administered.

Sub-acute gastritis is by no means a rare affection, and its occurs in two distinct forms—"one in which the malady is caused by a constitutional state, the effects of which are shown in a variety of other organs, as well as in the stomach; another in which it is due to causes connected chiefly or exclusively with this organ, which is submitted to an irritative process somewhat analogous to that typified by the gastritis of irritant poisoning."—Brinton, *On Diseases of the Stomach*, 1859, p. 101. The first of these forms is well illustrated in certain cases of scarlatina, in which, if death takes place between the third and seventh day of the disease, distinct marks of inflammation are seen in the stomach. The other variety, which is often of a chronic form, is best seen in cases of delirium tremens; the affection being sub-acute or chronic, according as it has been produced by a single prolonged debauch, or by a protracted habit of drinking spirits; the patient's final malady being induced by a deficiency of food, or the want of the ordinary stimulant. Purely chronic inflammation may be induced by various causes, of which the most common are the abuse of alcoholic drinks, habitual excess in eating, the eating of indigestible food, and the excessive use of irritating medicines.

The treatment of gastritis varies so much with each individual case, that we shall only lay down a few general principles. The first point is the removal of the cause; to be attempted in cases of irritant poisoning, either by the removal of the poison (by the stomach-pump or emetics, as, for example, sulphate of zinc), or by its neutralization by means of an antidote. In very severe cases, leeches may be applied to the epigastrium; but counter-irritants, such as turpentine on a hot moist flannel, or mustard-poultices, are

generally of more service. Continuous fomentation with water, as hot as can be borne, often gives great relief; while at the same time iced water, or small lumps of ice swallowed whole, usually relieve the thirst and mitigate the pain. Enemata of purgative materials, if the bowels are constipated, or of a soothing character (as thirty drops of laudanum in a little starch or gruel), if the bowels are irritable, may be prescribed with advantage. When the stomach begins to be able to retain food, it must be given in the form of a bland liquid, in small doses, at distant intervals. Chronic gastritis must be treated in much the same manner as indigestion (q.v.) The most essential point of treatment is the due regulation of the diet.

Ulcer of the stomach is the most important of the idiopathic diseases of that organ, both from its frequency, from the facility with which it may be detected during life, from the fact that at any period of its protracted course it may prove suddenly fatal, and from its being usually curable. The first and most characteristic symptom of this disease is pain, which commences as a mere dull feeling of weight or tightness, then gradually augments into a burning sensation, and at last assumes a gnawing character, and occasions a kind of sickening depression. This pain comes on in from two to ten minutes after the ingestion of food, and lasts for an hour or two; vomiting often ensues, after which the pain ceases. The place of its most common appearance and greatest intensity is the center of the epigastric region, or slightly below the free end of the ensiform cartilage of the sternum; and the painful spot is usually of a circular form, with a diameter varying from one to two inches. The pain in this region is succeeded, in the course of a few weeks, by a gnawing pain in the back, ranging in position from the eighth dorsal to the second lumbar vertebra, and most commonly lying between the two shoulder-blades. The pain in both the epigastric and the dorsal region is almost always much increased by pressure; it is also specially affected by certain kinds of food and drink, being increased by the ingestion of hard and indigestible substances, and lessened by a bland and pulpy diet. As a general rule, the pain is aggravated by tea, beer, and hot food; although exceptions occasionally occur. The next symptom in this disease is vomiting or regurgitation, expelling the food previously taken, or a glairy alkaline fluid. The vomiting usually occurs when the pain is most intense, and is a dangerous symptom, since it tends to starve the patient, and to increase the fatigue of an already weakened frame. At this stage the disease is sometimes terminated by the occurrence of perforation, ending in rapidly fatal peritonitis; and if this accident does not occur, the dyspeptic symptoms become complicated by hemorrhage from the stomach, sometimes so rapid that it distends the stomach and adjacent small intestine with a single gush, and causes fainting and almost immediate death; but more commonly occurring as a slow and intermittent drain of blood, giving rise to anemia. If death from the above causes (inanition, perforation, or hemorrhage) does not terminate the disease, the symptoms frequently subside in something like the inverse order in which they occurred, and recovery, often after many years' suffering, ensues. With regard to frequency of ulcer of the stomach, Dr. Brinton, who has carefully studied this disease, states that this lesion may be detected in (on an average) 5 per cent. of persons dying from all causes; that it occurs twice as frequently in females as in males, and that it is specially a disease of middle and advancing life—27 being the average age in females, and 42 in males. Nothing is known with certainty regarding the causes of this disease, except that advancing age, privation, mental anxiety, and intemperance so frequently coincide with it, that they may be regarded in some degree as producing it. In relation to treatment, strict attention to diet is of the first importance. When the symptoms are urgent, the patient should maintain the recumbent position, and should be fed on lukewarm milk, thickened with biscuit-powder, given in doses of one, or, at most, two table-spoonfuls every two hours. The pain is often relieved by the application of a mustard-poultice to the painful spot; and benefit is frequently derived from the internal administration of bismuth (in doses of ten grains), either given alone or combined with the compound kino powder (in five-grain doses). When there is hemorrhage small lumps of ice may be swallowed; and if all food is rejected by vomiting, beef-tea injections must be thrown into the lower bowel. Aperients are sometimes required, but they must be given with caution; and if castor-oil can be taken without increasing the pain or vomiting, it is the most harmless remedy of its class.

Cancer of the stomach is a disease of much interest, from its being obscure in its symptoms and difficult of detection in its early stage, frequent in its occurrence, and always fatal in its termination. The typical course of this disease is graphically sketched by Dr. Brinton in the following paragraph: "An elderly person perhaps hitherto free from dyspepsia, begins to suffer from a capricious, and soon a diminished appetite; which is by and by associated with occasional nausea, or even vomiting, and with a sense of uneasiness or distention of the stomach. His complexion, already pale and unwhole some, next acquires a muddy, yellowish, or faint greenish hue. His gastric symptoms now increase; often by a sudden and marked augmentation, which corresponds to what is in other cases their first appearance. Vomiting, if already present, becomes more frequent and urgent; local uneasiness deepens into pain; and both these symptoms are excited or increased by taking food. At a somewhat later period hemorrhage generally occurs, usually but scanty in amount, and therefore depending to a great extent on casual circumstances for its detection. About this time, a tumor often becomes perceptible

tible near the middle of the epigastric region of the belly. As the local symptoms increase, the cachexia of the patient also augments; and is evidenced not only by the color already mentioned, but also by debility and emaciation; and at last by prostration, which ends in anasarca, delirium, and death."—*Op cit.*, p. 225. From the records of 600 cases, Dr. Brinton finds that most deaths occur between the ages of 50 and 60 years. The form of cancer which most frequently attacks the stomach is the scirrhus or hard cancer. Out of 180 cases, scirrhus occurred in 130 (or nearly three-fourths of the whole), medullary or encephaloid cancer in 32, colloid in 17, melanotic deposit in 3, and villous cancer in 1. In the treatment of this formidable disease, more good is done by careful attention to the diet than by any medicine. Good milk or strong beef-tea thickened with biscuit-powder may be given in the same manner as recommended in ulcer; and milk mixed with a little old Jamaica rum will sometimes stay on the stomach when everything else is vomited. If there be pain, opiates must be given, and they may be prescribed either in the ordinary way, or as enemata, the latter having the advantage of not inducing constipation.

Hæmatemesis, or vomiting of blood, must be looked upon rather as a symptom than a disease. Thus, it may occur by the ulcerative destruction of the walls of a comparatively large blood-vessel, as in gastric ulcer and in cancer; but it generally is of the kind termed capillary. The latter kind of hemorrhage happens under various circumstances, of which the following are the principal: 1. The bleeding may be idiopathic, or unaccompanied by any structural change. This variety is extremely rare. 2. It may take the place of some habitual hemorrhage, or, in other words, be vicarious. Thus it frequently takes the place of the menstrual discharge. 3. It is often a consequence of disease or injury of the stomach; for example, it frequently occurs after the ingestion of strongly irritant poisons, or even an immoderate dose of alcohol into the stomach. 4. It may be a consequence of disease in adjacent viscera, occasioning an overloading of the veins of the stomach; thus it is frequently caused by enlargement of the spleen, and occurs in those states of the liver in which there is obstruction of the portal circulation; and under this category we must place the gastric hemorrhage which not unfrequently occurs in the advanced periods of pregnancy, in consequence of the pressure exerted by the enlarged uterus on the venous circulation of the abdomen. 5. It may result from changes in the composition of the blood, such as occur in scurvy, purpura, and yellow fever. The treatment must be directed against the disease on which the hemorrhage depends, rather than against the mere symptom; but from whatever cause it arises, if it is proceeding to a dangerous extent, the patient should be kept perfectly quiet in bed, and should swallow small pieces of ice. Hot applications may also be applied to the extremities, with the view of directing the blood to those parts. The medicines most likely to be of service are acetate of lead, gallic acid, dilute sulphuric acid, and oil of turpentine; but they should only be given on medical authority.

Some of the other affections of the stomach are discussed in special articles. See CARDIALGIA, INDIGESTION, SARCINA, etc.

STOMACH-PUMP, an instrument used to remove poisons from the stomach, to feed persons who attempt to starve themselves, etc. It is a syringe with a flexible tube, inserted into the stomach through the œsophagus, and by which fluid is injected or removed.

STOMAPODA (Gr. mouth-footed), an order of malacostracous crustaceans, to which *squillidae*, glass-crabs, etc., belong. All of them are marine. They are most abundant in tropical seas, but some are found in those of temperate parts of the world. They have seven or eight pair of legs, mostly near the mouth. The gills are external, adhering to the appendages beneath the abdomen, which is elongated, and terminates in an extended tail-fin. The rings which bear the eyes and the antennæ are not confounded with the rest of the head, as in the *decapoda*, but are more distinct. The carapace often leaves the latter rings of the thorax exposed. The heart is very different from that of the *decapoda*, assuming the form of a long cylindrical vessel, which extends throughout the length of the abdomen.—The stomapoda inhabit deep parts of the sea, many of them living at the bottom, while some, as glass-crabs, are found floating at the surface.

STOMATA (Gr. mouths), are minute openings in the epidermis of leaves and other green parts of plants exposed to the air, communicating with intercellular spaces. Their existence was first noticed by Grew, who described them in his *Anatomy of Plants* in 1682. They are generally formed by two semilunar cells, which are as lips to the orifice, and are filled with green matter; but sometimes the cells arranged around them are more numerous. They are generally of an elliptical form, but sometimes circular, and sometimes quadrangular. These differences are very characteristic of particular species, genera, or orders of plants. In a moist state of the atmosphere, they are open; but when it becomes dry they are closed, or nearly so. It appears that they are organs of transpiration, and that their opening and closing according to the moisture or dryness of the atmosphere regulates it in a manner suitable to the requirements of the plant. They do not occur in any part of the plant covered by the soil, nor in submerged leaves, nor on the lower sides of floating leaves. Succulent plants have very few of them; so that these plants retain for a long time the moisture which they have imbibed, and are thus adapted for living in a dry atmosphere. Stomata are generally most abundant on the

under side of leaves; but in leaves which grow vertically, they are often almost equally numerous on both sides. In general they are irregularly placed; but in grasses and many other endogenous plants with parallel-veined leaves, they are in regular rows; and in some other plants they occur in little groups. The number in a square inch varies from 200 in the mistletoe, to almost 450,000 in the under side of the leaves of *solanum sanctum*.—Stomata are not found in mosses, lichens, algæ, and fungi; but they exist in some of the *hepaticeæ*, as in *marchantia*, in which their structure is more complex than in the higher plants; each of them consisting of a kind of shaft, composed of four or five rings placed one upon the other, every ring made up of four or five cells, and the lowest ring apparently regulating the aperture by the contraction or expansion of the cells which form it.

STONE, a weight in use throughout the n.w. and central countries of Europe, but varying much in different countries. It is chiefly employed on the continent for weighing wool, hemp, flax, and feathers, the flax-stone containing twice as many pounds as the one used for wool and feathers. In all the principal commercial states of Germany, the stone (of flax) is the $\frac{1}{2}$ of a cwt. (centner = 100 or 112 lbs.), i.e., 20 lbs., in Prussia and the Zollverein, Hamburg, Lübeck, and Bremen; 22 lbs. in Austria, etc.; in Britain it is the $\frac{1}{2}$ of a cwt., or 14 lbs.; while in Sweden it is equivalent to 32 lbs. In Great Britain, though the stone of 14 lbs. is the only legal imperial weight of the kind, stones of other values are in regular use, as a stone of 24 lbs. for wool, and one of 8 lbs. for butcher-meat.

STONE. See CALCULUS and LITHOTOMY.

STONE is used for a great variety of purposes—for building, paving, millstones, grindstones, hones, ornamental purposes, etc. Besides what is said under special headings (see BUILDING STONE, QUARRY, MILL, GRINDSTONES, HONES, MARBLE, GRANITE, SLATE, etc.), the following general remarks may be added here. The desirable properties in a building-stone are, that it should be compact, insoluble in water, not easily altered by the atmosphere, and not liable to take on a vegetable coating. These qualities depend upon its chemical composition and on its mechanical structure. Building stones may be divided into three classes—siliceous, calcareous, and composite. Siliceous stones (including granite, porphyry, gneiss, greenstone, basalt, sandstone, slate, serpentine, etc.), and containing from 45 to 99 per cent. of silica) are, as a general rule, the most durable for building. Their durability is affected by certain of their ingredients, as by the felspar in granite, and salts of iron in sandstone. Calcareous stones (simple limestone, travertine, marble, etc.), are slightly soluble in pure water, and more so in carbonic acid water; they are liable to splinter by water freezing in their pores, are acted on by acid gases (e.g., the sulphurous acid gas produced by the combustion of most kinds of coal), and are somewhat liable to be stained by minute plants. Still, some of them are lasting enough in a country atmosphere. The failure of the magnesian limestone selected for the British houses of parliament is a good instance of a stone lasting for centuries in a country church, and yet quite unable to withstand the wasting action of the atmosphere of a great city. Composite stones, in which neither the silica nor the lime greatly predominates, are unimportant.

The most exhaustive account of the building stones of the British islands is given in the parliamentary blue book embodying the report of the commissioners appointed to select a stone for the houses of parliament, published in 1839. Much scientific information regarding all kinds of stone will be found in the catalogue of the rock specimens of the museum of practical geology, London. See STONE, BUILDING.

STONE, a co. in n. Arkansas, drained by the White and Little Red rivers; pop. '90, 7043, with colored. The surface is uneven. The soil is fertile. The principal productions are corn, cotton, tobacco, and livestock. Area, 619 sq. m. Co. seat, Mountain View.

STONE, a co. in s.w. Missouri, adjoining Arkansas, drained by the James and White rivers, and traversed by the Chicago, Milwaukee, and St. Paul railroad, about 516 sq. m.; pop. '90, 7090, chiefly of American birth. The surface is uneven and heavily timbered. The soil is fertile. The principal productions are corn, wheat, tobacco, wool, and cattle. Iron and coal are found. Co. seat, Galena.

STONE, a market t. of Stafford, stands 7 m. n.n.w. of the town of that name, on the left bank of the Trent. Shoemaking, tanning, malting, and brickmaking are the chief branches of industry. Near the church are some remains of an Augustinian monastery. Pop. '91, 5754.

STONE, ARTIFICIAL. Artificial stone, properly speaking, would include burned clay wares used for building purposes, as bricks, terra-cotta (q.v.), etc., as well as the various cements. We shall confine ourselves here to a description of the silicious artificial stone produced by the cementing properties of soluble alkaline silicates on sand, which has excited a great deal of attention within the last 30 years. So far back as 1825, Prof. J. N. von Fuchs of Munich published a paper on various applications of these silicates, and so laid the foundation of a new industry. To M. Kuhlmann of Lille, however, is mainly due the merit of working out the practical application of the soluble silicate of potash or soda to the manufacture of hydraulic lime, cement, and especially to artificial stones. Mr. Frederick Ransome of Ipswich has also done great service by his success-

ful exertions in producing an artificial stone from the same substances. The process, as at first practiced by Mr. Ransome, consisted in mixing the gelatinous silicate of soda with sand and a little powdered glass and clay, in the proportions of sand, 10 parts; glass, 1 part; clay, 1 part; and silicate of soda, 1 part. These ingredients were thoroughly incorporated in a pug-mill, and brought to the consistency of putty. The plastic nature of the substance at this stage allows it to be molded with ease into an endless variety of forms, even of an elaborately ornamental kind. After leaving the molds, the objects are dried in close ovens, and then removed to kilns, where they are fired at a gradually increasing temperature, which finally reaches a red heat. In the kiln, the goods are bedded up in dry sand, to prevent any of the twisting or loss of shape which so commonly disfigures large objects in baked clay. When the firing is completed, the material is in the state of a semi-vitrified mass, with the appearance, properties, and composition of a fine sandstone.

A later patent of Mr. Ransome's consists in producing a hard and durable material altogether without baking, by effecting a double decomposition with the silicate of soda and the chloride of calcium. Such materials as sand, chalk, or other minerals are intimately mixed with a proper quantity of a solution of silicate of soda, this being secured, as before, by the operations of a pug-mill. In this plastic condition, they are molded into any required form, after which they are saturated with a solution of chloride of calcium. The silica combining with the calcium forms at once an insoluble silicate of lime, which cements into a firm mass all the particles of sand, lime, etc., used in the composition. The chlorine, on the other hand, combines with the soda to form common salt (chloride of sodium), which can be readily removed by washing.

The objects into which artificial stone is manufactured are very miscellaneous; whatever, in fact, is made of real stone can also be formed in the artificial. Among the more prominent applications of it, we may notice grindstones, millstones, tombstones, monuments, chimney-pieces, balustrades, fountains, vases, and statuary.

STONE, AMASA, b. Charlton, Mass., 1818; early engaged in the building of railroads and bridges; superintendent of the New Haven, Hartford, and Springfield railroad, 1845; one of the contractors for building the Cleveland and Columbus, and the Cleveland, Painesville, and Ashtabula railroads. Mr. Stone made improvements in the machinery and construction of railroads, and built car-factories and rolling-mills at the west. Mr. Stone, who resided at Cleveland, Ohio, made a donation of \$600,000 to Adelbert college of the Western Reserve university at Hudson, on condition of its removal to Cleveland,—an offer that was accepted. He d. 1883.

STONE, ANDREW LEETE, D.D., b. Conn., 1815; graduated at Yale college, 1837; professor in the deaf and dumb institution in New York for three years, and also studied theology; was for a time connected with the American Sunday-school union; ordained pastor of the South church (Congregational), Middletown, Conn., 1844; pastor of Park street church, Boston, 1849-65; was settled, 1866, in San Francisco, Cal. He has published *Service the End of Living*, and various discourses. In Boston he was noted as a pulpit orator, and has had much influence on the Pacific coast.

STONE, CHARLES P., b. Greenfield, Mass., 1824; graduate of West Point, 1845; assistant professor of ethics, 1845-46. He served in all the battles of the Mexican war from Vera Cruz to the capitulation of the city of Mexico. In 1851 he was assigned to the Pacific coast as chief of ordnance, and superintended the building of the arsenal at Benicia. He left the army in 1856; was a banker in San Francisco in 1856-57. He explored Sonora and Lower California in the service of the Mexican government. In 1861, under Gen. Scott, he organized and drilled the militia of the district for the defense of Washington. With the rank of col. of the 4th infantry and brig.-gen. of volunteers he fought under Gen. Patterson on the Shenandoah; also engaged on the upper Potomac. In 1862 he was detained for a few months in Fort Lafayette, in consequence of some reports to his disadvantage. In 1863 he took part in the siege of Port Hudson, and served soon after as chief of staff to Gen. Banks. After having been engaged in all the battles of the Louisiana campaign and commanding a brigade in the army of the Potomac, he was mustered out of the volunteer service, 1863, and in 1864 resigned his commission in the regular army. He was brig.-gen. and chief of staff in the service of the khedive of Egypt, 1870-82; superintended the erection of Bartholdi's statue, New York harbor; d. 1887.

STONE, DAVID MARVIN, b. Oxford, Conn., 1817; son of Dr. John Noah S.; engaged in mechanical and mercantile pursuits till 1849, when he succeeded David Hale on the editorial staff of the New York *Journal of Commerce*, of which paper he has been editor-in-chief for more than 20 years. He was also pres. of the New York associated press. In addition to much fugitive work, he has pub. *Frank Forrest* and *Memorial of an Only Daughter*. He d. April 2, 1895.

STONE, HORATIO, abt. 1810-75; b. New England; received a classical education; studied medicine and practiced in New York; turned his attention to art; became a sculptor and settled in Washington, 1846. He wrote for the press in prose and verse. He lived in Italy, 1856-57, returned to this country, and on a second trip abroad died in Carrara. His fame rests chiefly on his statues of Hamilton, Benton, Hancock, and Tanev, executed by order of the U.S. government.

STONE, JAMES KENT, D.D., b. Boston, 1840; graduated at Harvard college, 1861; studied in Italy and Germany, 1861-63; was ordained in the Protestant Episcopal church; professor of Latin, Kenyon college, Gambier, Ohio; afterward of mathematics, and became its president, 1867; elected president of Hobart college, Geneva, N. Y., 1868. In 1870 he became a Roman Catholic, and joined the association of missionary priests of St. Paul, New York. He published *The Invitation*, a statement of the reasons for his change.

STONE, JOHN HOSKINS, 1745-1804; b. Md.; entered the revolutionary army, in which he rose to be col. He was compelled to leave the service in 1779, in consequence of wounds received at the battle of Germantown. He was afterward a clerk in the state department, a member of the Maryland executive council, and governor of the state, 1794-97.

STONE, JOHN SEELY, D.D., 1795-1882; b. Mass.; grad. at Union college, 1823; studied in the General theological seminary, and was ordained in the Episcopal church, 1826; rector Christ church, Brooklyn, N. Y., and St. Paul's church, Boston, 1832-41; lecturer in Philadelphia divinity school; dean of the theological seminary, Cambridge, Mass., 1867-75. He published *The Mysteries Opened*; *The Christian Sabbath*; *The Church Universal*; *The Contrast*; *Life of James Milnor*; *Life of Bishop Griswold*; *The Christian Sacraments*. His ministrations were greatly prized in successive parishes.

STONE, LUCY. See BLACKWELL, LUCY STONE.

STONE, SAMUEL, 1602-63; b. England; graduated at Cambridge, 1627; curate of Stisted, Essex, 1627-30; became a Puritan, and was persecuted; emigrated to America, 1633, with Cotton, Hooker, and 200 others; was an assistant to Mr. Hooker, at Cambridge, Mass., 1633-36; removed to Hartford with Hooker, who later succeeded him. The latter part of his life was embittered by a dispute with Mr. Goodwin, a ruling elder, resulting in a division of the church. He published a *Discourse on the Logical Notion of a Congregational Church*, and left in MS. a valuable body of divinity.

STONE, THOMAS, 1743-87; b. Md.; studied law at Annapolis, Md. After his admission to the bar, 1764, he practised in Fredericktown, and later in Charles county. He was a member of the colonial and continental congress, 1775-79; warmly supported the movement for independence, and served on important committees. In 1783 he was again elected to congress.

STONE, WILLIAM LEETE, 1792-1844; born in New York state; a printer who edited several newspapers, including the *Albany Daily Advertiser*, the *Hartford Mirror*, and the *New York Commercial Advertiser*. He was superintendent of the New York common schools, 1843-44. Among his numerous works are *Tales and Sketches* (1834); *Essays on Social and Literary Topics* (1835); *Letters on Animal Magnetism* (1837); *Life of Joseph Brant* (1838); *Border Wars of the Revolution* (1839); and *Poetry and History of Wyoming* (1841).

STONE, WILLIAM LEETE, Jr., b. New York, 1835; educated at Brown university and the Albany law school. Among his writings are: *Life and Writings of Colonel William L. Stone* (1866); *History of New York City* (1872); and *Centennial Sketches* (1876). He has been an editor and a publisher.

STONE, WILLIAM OLIVER, 1830-75; b. Conn.; studied painting under Nathaniel Jocelyn in New Haven, and settled in New York in 1851. In 1854 he exhibited his first picture, "The Mantilla," at the national academy, of which he was made an academician in 1859. He was very successful as a portrait painter of women and children.

STONE-BORERS, certain species of lamellibranchiate mollusks belonging to the families *pholadidae*, *gastrochaenidae*, *mytilidae*, *veneridae*, and probably some others, which have the power of perforating stone. These animals are allied only by class characteristics, being all lamellibranchs. Their generic characters differ much, and their methods of excavations into rocks are various; but it is believed that the majority produce their mechanical effects by grinding with the anterior portions of their shells. There are also certain worms and echinoids which bore into rocks.

STONE, BUILDING (see BUILDING-STONE). The great merits of a stone for building purposes are easy working, long lasting, equality in color and structure, strength, and, not least important, cheapness. We have in this country almost unlimited supplies of excellent stone of every kind; but we are not really a stone-building race for two reasons—exorbitant freights and expensive labor. The divisions of stone from this point of view are not those of the science of petrography, owing to the methods of cutting and laying. Stones are laid in a wall sometimes roughly just as found, only taking care to get a plumb face; this is rubble-work. Again, they may be laid in lines depending on the thickness of the stone, but with butt-joints unequally distributed—coursing; or the courses may be leveled up only at every three or five rows, the joints between not necessarily vertical—random-coursing; or the stone is laid in courses of blocks, butt-joints at stated intervals—ashlar. The strength and the life of a stone depend upon its being laid upon its bed (the strata in a quarry are not always parallel with the horizon), and its having a level, true surface for pressure both received and distributed. It is, then, of great moment to the workman whether the stone can be separated parallel to the

bed—splittage; and also at right angles to it—cleavage. He divides, then, his material into freestones which split and cleave (gneiss and some trap also); slates which split (also basalts and some gritstones); limestones which cleave (some granites as well); tough stones which neither split nor cleave—granites and conglomerates (but here belong chalks, though so soft as to be good, in our climate, for inside carving only). The best construction has always been done in the hardest stone, and it is necessary to see how such an intractable material is reduced to shape. The workman knows two distinctions—of country-stone and quarry-stone. But the first, often occurring in boulders, is likely to be one of the toughest of all, though usually they are the easily reached outcrops of strata which are more likely to be sandstone or limestone. All quarries are poor and mottled in the top-beds, but the stone becomes better as it descends; also, more beds and of different thicknesses are struck, the only stones not lying in beds being chalk, conglomerates, and some granites, though even the latter have at intervals a definite line of split. The three heaviest tools in use are the hammer, the axe, and the pick. The block being reduced to a nearly rectangular shape, the edges are got to line with the axe, and a broad level edge of the width of a tool, called a draft, is put all around the face of the stone and brought true by the square and the level. The bossed, rectangular panel so formed may be left quarry-faced, picked, axed, or hammered; the last being a level surface pitted with small holes if made by the bush-hammer, or scored with parallel lines if made by the patent-hammer. This is the slow process of reducing to shape the tough stones. Moldings and ornaments are roughed out with the pitching-tool, a pointed chisel; with the mash-point, a chisel with one level; and finished with drafting and beveled chisels and tools of the necessary shapes and curves. The work is finally rubbed and polished, with emery and pumice-stone, if desired. This process is evidently much shortened when machinery is used. The saw for marbles is a plain strip of iron fed with sand; that for harder stones is of copper fed with emery. Freestones are cut with a grub-saw having coarse teeth at intervals; and chalk-stones with a heavy hand-saw with hooked teeth. Heavy stones are polished by power-rubbers, and manageable ones by themselves, being revolved over a large rubbing-table. Freestones and limestones can be planed by machinery, also turned; but no machine has yet succeeded in planing granite, though balusters have been roughly turned, or rather chipped to shape. The qualities of a building-stone to be tabulated are its color, strength, weight, absorption, and place of production, together with any peculiarities. The figures which follow are mostly due to the report of Gen. Gillmore on the “Building-stones of the United States.” Some foreign ones in general use are included.

------------------	-------------------	-------	------	------

Red, purple, and green slate are found on Lake Champlain and in Vermont; black and deep purple in New Jersey and Pennsylvania; fine colored marbles are found near Lake Champlain and the St. Lawrence River, in West Virginia, in Tennessee, and in California. In the above table all crushing strength is taken on the bed. When that taken on edge is greater—very rarely—it shows a formation like that of a gneiss. A heavy stone, of high crushing strength and no absorption, is sure to be a good building-stone, unless it contain iron. If not homogeneous, like the Chaumont limestone, usually called a granite, which shows shells when rubbed, it should never be more than fine-worked. All stones are bettered by a certain exposure before laying—a weathering; and for sandstones it is indispensable. Chalks, which harden by exposure, can be cut with a light mallet when built in the wall.

STONE-CHAT, *Saxicola rubicola* (see CHAT), one of the most common of the British *syliadae*, a pretty little bird, rather smaller than the redbreast, black on the upper parts and throat in summer; the breast of a dark reddish color; some white on the sides of the neck, the wings, and the tail. It makes its nest on the ground, or on a low branch. Some stone-chats spend the winter in Britain, but the greater number migrate to more southern regions.

STONECROP. See SEDUM.

STONE-CUTTING AND DRESSING MACHINES. Stone is a substance which in none of its varieties is easily operated on by machinery, owing chiefly to its brittleness, its unequal hardness, and the natural cracks which so frequently impair its solidity. Accordingly, though many ingenious machines have been invented for working stone, it is as yet only in some of the plainer kinds of work that they can be said to have entirely superseded hand operations.

Some stones and slates are soft enough to be cut with ordinary toothed saws much in the same way as wood is cut. More generally, however, the sand-saw is employed, which we shall presently describe in noticing marble-cutting. For the cutting of com

mon kinds of stone, which are not to receive a fine polish, a machine, which promises to be very efficient, has been recently patented by Mr. George Hunter of Maentwrog, Caernarvon, and is now in operation at various large quarries, both of stone and slate. The cutting portion consists of a circular disk, round the circumference of which a number of pointed steel tools are fixed into sockets, thus giving it the appearance of a large toothed saw. This machine will cut sandstone at the rate of 5 to 6 in., slate at 3 in., and soft limestone at 3 in. per minute, supposing these to be in blocks each 2 ft. thick.

So far as the sawing or slicing of stones is concerned, the tendency of late years is to rely on the use of the diamond—the dull black variety which is of no use as a gem. Some American stone-cutting machines have saws with teeth set with these diamonds, and are said to cut ordinary sandstone at the rate of 75 sq. ft. per second for each saw. Machines for dressing the face of stones by means of a series of chisels in imitation of the handwork of the mason have recently been tried and have given fair results.

It is considerably more than a century since machinery for sawing and polishing marble was first established at Ashford, near Bakewell, in Derbyshire, that county being still the seat of the principal marble manufacture of England. Marble is cut into slabs by means of a series of thin plates of soft iron used like saws, but having no teeth. The saw-blades are fixed into a rectangular frame, to which a reciprocating horizontal motion is given. The block of marble to be cut rests on a carriage below the frame, and a small rill of mixed sand and water is constantly falling into the saw-cuts.

After the marble has been sawn into slabs it is cut up into narrow pieces, when so required, by means of small circular saws with smooth edges, sand and water being employed as above.

The sawn slabs are next submitted to the grinding process. This, for pieces of moderate size, is usually done upon a large circular cast-iron plate, called a *sanding-bed* or *grinding-bed*, mounted upon an upright spindle, and supplied with sand and water. The workman places the piece of marble with its face downward upon the grinding-bed, and exerts the proper amount of pressure. The marble is held in its place by means of guide-rods stretched across the plate. Slabs too large to be manipulated in this way are ground with plates of iron operating upon their surface.

The marble, when properly ground, is polished on a polishing bed or table, with an arrangement for securely fixing it while the rubbing is being proceeded with. The polishing rubbers are sometimes blocks of wood faced with felt, and sometimes bunches of hemp compressed between two side-plates. They are attached to a swing-frame with a pendulum-like motion, which draws them backward and forward over the surface of the marble. Flour emery is used to charge the rubbers in the first instance, and putty-powder (oxide of tin) for the finishing polish. Instead of emery sometimes the fine-grained stone known as water of Ayr stone is used to prepare the marble for the putty-powder.

Cylindrical objects, such as columns or vases, are first formed roughly into shape with a hammer and chisel, and then turned, with a pointed steel tool, upon a lathe, to which a slow motion is given. When thus brought to an accurate form, a rapid motion is given to the lathe, and the tool-marks ground away by the use of coarse, and then fine, and still finer sandstones—the polishing being completed with emery and putty-powder while the object is still upon the lathe.

Machinery is also applied to the production of flat objects with curved and molded outlines. The machine for this purpose operates by the use of a rotatory cutter, which is guided in its action by a template formed accurately to the intended shape of the article.

The cutter is of steel or stone, and is attached to the lower end of a spindle driven by beveled wheels. There is a flange which allows the cutter to penetrate the marble till it reaches the template and no further. In the process of cutting the marble is constantly drawn up against the cutting-tool by two weights, the one pulling the table in one direction, the other the carriage on which the table rests, in a direction at right angles to the former, thus compelling the cutter to follow the outline of the template. The shape of the cutting-tool is, of course, exactly the reverse of the molding to be formed.

In the cutting and polishing of granite, the machinery and processes are so nearly the same as those employed for marble, that it is unnecessary to describe them separately. Suffice it to say, that all objects to which the sawing apparatus cannot be applied, require to be worked to shape with great care by means of steel chisels and iron mallets, which only remove small portions at a time. Owing to the great hardness of the material, any defect in the chiseling greatly increases the labor of polishing. So slow, indeed, are the operations with granite, that a saw-blade will not cut through an inch in depth during a whole day, and a good-sized sawn slab will take a week to polish.

STONE-FLY, *Perla*, a genus of neuropterous insects, of the tribe or family *planipennes*. The hind wings are broader than the fore-wings, and folded at the inner edge. The body is elongate, narrow, and flattened; the wings close horizontally on the body; the abdomen is generally terminated by two bristles (*setæ*). The larvæ are aquatic, and much resemble the perfect insect, except in the want of wings. A number of species are common in Britain, and are well known to anglers as an attractive lure for fishes.

STONE-FRUITS, in popular language, are those fruits which are botanically designated *drupes*, and in which the rind is fleshy, and the putamen bony. Many of the finest dessert fruits are of this description. Those best known in temperate climates generally belong to the natural order *rosaceæ*, sub-order *amygdaleæ*, the order *drupaceæ* of Lindley, as the peach and nectarine, plum, cherry, apricot, etc. In tropical countries, many stone-fruits occur, belonging to *chrysobalanaceæ* and other natural orders.

STONEHAM, a town in Middlesex co., Mass.; on the Boston and Maine railroad; 13 miles n. of Boston. It was incorporated in 1725; has street railroad connection with Woburn and Boston, a high school, public library, national and savings banks, weekly newspapers, and an assessed property valuation of over \$4,300,000; and is noted for its extensive manufactories of shoes and its large tanneries. Pop. '90, 4890.

STONEHAVEN, a sea-port t. of Scotland, capital of the co. of Kincardine, and a station on the railway from Dundee to Aberdeen, is situated on a rocky bay at the mouth of Carron Water. It is divided into an old and new town, on different sides of the river, and connected by a bridge. The harbor can admit only small vessels. Stonehaven has very considerable haddock and herring fisheries, and some slight manufactures. Pop. '81, 3,957. Two miles s., on a projecting rock, stands the famous castle of Dunnotar, once the residence of the Earls Marischal.

STONEHENGE (Sax. *Stanhengist*, hanging or uplifted stones), a very remarkable structure, composed of large artificially raised monoliths, situated on Salisbury plain, two miles from the town of Amesbury, in Wiltshire. Its neighborhood abounds in sepulchral tumuli, in many of which ancient British remains have been found. The fabric of Stonehenge, which was comparatively entire in the early part of the present century, has been so much defaced in recent times as to be at first view little more than a confused pile of moss-grown stones; but a minute inspection will still enable one to trace its original form. When entire, it consisted of two concentric circles of upright stones, inclosing two ellipses, the whole surrounded by a double mound and ditch circular in form. Outside the boundary was a single upright stone, and the approach was by an avenue from the n.e., bounded on each side by a mound or ditch. The outer circle consisted of 30 blocks of sandstone, fixed upright at intervals of $3\frac{1}{2}$ ft., and connected at the top by a continuous series of imposts, 16 ft. from the ground. The blocks were all squared and rough-hewn, and the horizontal imposts dovetailed to each other, and fitted by mortise-holes in their under sides to knobs in the uprights. About 9 ft. within this peristyle was the inner circle, composed of 30 unhewn granite pillars, from 5 to 6 ft. in height. The grandest part of Stonehenge was the ellipse inside the circle, formed of 10 or 12 blocks of sandstone, from 16 to 22 ft. in height, arranged in pairs, each pair separate, and furnished with an impost, so as to form 5 or 6 trilithons. Within these trilithons was the inner ellipse, composed of 19 uprights of granite similar in size to those of the inner circle; and in the cell thus formed was the so-called altar, a large slab of blue marble.

There has been much speculation regarding the origin and purpose of Stonehenge, which are still involved in much obscurity. A curious legend, first found in the *British Chronicle* of the 10th c., and repeated by Geoffrey of Monmouth and Giraldus Cambrensis, ascribes it to Emrys or Ambrosius, the last British king, who, in the 5th c., aided by the incantations of the magician Merlin, is said to have erected it in memory of 460 Britons, who were murdered by Hengist the Saxon. In modern times, the most prevalent opinion has been that, in common with other similar structures elsewhere, it was a temple for Druidical worship; but this belief has been somewhat shaken by the discovery of the sepulchral character of many other monuments, which had been also presumed to be Druidical. The circular form has suggested the idea of a connection with the worship of the sun; and Stonehenge may possibly have been used for the religious rites of various successive races and creeds; and also as a court of justice or battle-ring for judicial combats. The outer circle is evidently of a much later date than the rest, and seems to belong to a period when iron tools were in use. See **STANDING STONES**.

STONEHOUSE, EAST, a parish of Devonshire, included within the limits of the parliamentary borough of Devonport (q.v.), and forming in effect a portion of Plymouth (q.v.). Among other government establishments, it contains the Royal William victualling yard, naval hospital, and marine barracks capable of accommodating 1500 men. Pop. of parish '91, 15,401.

STONEMAN, GEORGE, b. N. Y., 1822; graduated at West Point, 1846, and was commissioned in the cavalry. In 1861 he was in command of Fort Brown, Texas, and refused to obey Gen. Twiggs's order to surrender the government property in his charge to the secessionists, but evacuated the place and brought his command to New York on a steamer. He took part in the battle of Williamsburg and the second battle of Bull Run, and commanded the 3d corps at Fredericksburg. In the Richmond campaign Gen. Stoneman had command of the Ohio cavalry. He was also engaged in the movement on Atlanta, commanded the military district of e. Tennessee, and captured Salisbury, N. C., and Asheville. He retired from the army in 1871 with rank of col. and brevet rank of maj.-gen.; resigned, 1882; governor of California, 1883-87. Died Sept. 5, 1894.

STONE PERIOD. See **BRONZE**, **AGE OF**.

STONE-POCK, an old name for a variety of modified small-pox, in which the vesicles dried up into hard tubercles instead of proceeding onwards to maturation.

STONE, PRESERVATION OF. The mechanical preservation of stone can be effected to a great extent by coating the surface with boiled linseed oil, or with oil-paint; but these methods are not much in favor, as they destroy the crystalline appearance which constitutes the beauty of most natural stones. As promising a better result, many experiments have been tried, especially of late, with certain chemical solutions that are not likely to mar the inherent beauty of a stone. The substances which have been most used are those soluble silicates which we have referred to under **STONE, ARTIFICIAL**. The earlier process of Kuhlmann consisted in coating the surface with a soluble silicate of soda or potash, which is also known by the names of soluble glass, water-glass, and flint liquor. This was applied with a brush, and silification was produced by the silica of the solution entering into combination with the lime of the stone; but this took a considerable time, so that, on an exposed front, it was liable to be washed out before the proper hardening took place. The later process of Ransome consists in cleaning the surface of the stone from extraneous matter, and then applying alternate solutions of the above alkaline silicate and chloride of calcium, which forms an insoluble silicate of lime in the pores of the stone. This plan has been tried with a portion of the new houses of parliament many years ago, and is now extensively used in London, Edinburgh, Glasgow, and elsewhere. Ransome's process is indeed practically the only one in use. But the preservation of the houses of parliament has been the subject of inquiry since this invention was applied to them; and the committee which sat did not succeed in discovering any preserving agent which they felt justified in proposing. The chemists engaged in this inquiry selected, from a vast number of proposals then made, the following processes, as claiming a careful investigation: 1. Application of silicates of the alkalis, in various states of concentration; 2. Application of silicates, in conjunction with various saline compounds, intended to produce double decomposition; 3. Application of hydrofluoric or hydrosilicic acid, or their saline compounds; 4. Application of phosphoric acid and acid phosphates; 5. Applications of solutions of the alkaline earths, or their bicarbonates, in water.

STONE RIVER, BATTLE OF. See **MURFREESBORO**.

STONEWALL, a co. in n. western Texas, watered by the Brazos river; 900 sq. m.; pop. '90, 1024. Co. seat, Rayner.

STONEWALL, a magisterial dist., Rockingham co., Va. Pop. '90, 6764.

STONEWALL JACKSON. See **JACKSON**, **THOMAS JONATHAN**.

STONE-WARE. See **POTTERY**.

STONINGTON, a town and port of entry in New London co., Conn.; on Long Island sound and the New York, New Haven, and Hartford railroad; 12 miles e. of New London. It was incorporated in 1658; contains the borough of Stonington (incorporated 1801) and the villages of Mystic, Old Mystic, and Pawcatuck; and has a fine harbor, high schools, an English and classical institute, public library, public park, containing guns used in the successful defense of the town against the British fleet in 1812, a national bank, and weekly newspaper. It is on the line of regular steamboat communication between Providence, R. I., and New York. The manufactures include machinery, printing-presses, and woolen and velvet goods. Pop. '90, 7184.

STONY POINT, a town and village in Rockland co., N. Y.; on Haverstraw bay (Hudson river), and the New Jersey and New York, the New York, Ontario, and Western, and the West Shore railroads; 42 miles n. of New York. It was fortified by Americans early in the revolutionary war, captured by Sir Henry Clinton, 1779, and garrisoned; retaken by Gen. Anthony Wayne, July 16, 1779, with 1200 men in his command, by a sudden midnight attack, cutting off the sentries, and carrying the fort at the point of the bayonet, under a heavy fire of musketry and grape-shot, capturing 543 officers and men; American loss, 15 killed and 83 wounded; British, 63 killed. This was called by Gen. Charles Lee not only the most brilliant assault in the whole war on either side, but the most brilliant in history; the assault of Schveidnitz by Marshal Laudon he considered inferior to it. The simultaneous attack on Verplanck's Point being unsuccessful, the Stony Point works were destroyed and abandoned in obedience to Washington's orders. It has several churches, schools, and manufactures of brick and lime. Pop. '90, town, 4614.

STOOL OF REPENTANCE, the name ordinarily given in Scotland to a low stool conspicuously placed in front of the pulpit in churches, on which persons who had become subject to ecclesiastical discipline for immoral conduct were required to sit during public worship, in profession of their penitence, or on which they stood at the close of the service to be "rebuked" by the minister. It was also familiarly called the *cutty* stool, a term applied to small stools of similar form, common in houses, but which came to be often employed in conversation and in humorous verses with special reference to that which stood in the church. Transgressions of the seventh commandment being far more frequently the cause of occupying the stool of repentance than offenses of any other kind, the jokes which abounded on the subject of this piece of church-furniture were neither indicative of a pure morality nor calculated to promote it.

STOP, or **REGISTER**, a name given to the different ranges of pipes in an organ. Each stop consists of a series of pipes, of the same quality of tone, extending throughout the whole or a large part of the compass of the instrument, and furnished by a draw-stop or knob, on drawing which out, the air is admitted to the particular stop, so that the keys will play on pipes of that character. Some of the stops do not give the note which corresponds in pitch with the key struck, but a note an octave or two octaves lower, or one of the harmonics higher in pitch. Compound or mixture stops consist of more than one row of pipes to each key, corresponding to the different harmonics of the ground tone. The stops of different organs vary much in number and kind; a very large number are to be found in many of the organs in Germany and Italy. See **ORGAN**.

STOPPAGE IN TRANSITU is a valuable right or privilege of a vender of goods to resume possession, after he has parted with them under a contract of sale, and before the goods have reached the vendee. It occurs when goods are consigned entirely or partly on credit from one person to another, and the consignee becomes bankrupt before the goods arrive. In this event, the consignor has a right to direct the captain of the ship or other carrier to deliver the goods to himself or his agent instead of the consignee, who has thus become unable to pay for them. This right was first allowed as equitable by the court of chancery, and the courts of common law followed the example. There are certain circumstances, however, in which the right to stop *in transitu* may be defeated, as where the consignee of the goods indorses the bill of lading to a *bonâ fide* indorsee. When the vendee has appointed the carrier who is to receive the goods, their delivery to the carrier is treated for many purposes as delivery to the vendee himself; yet it is not too late for the vendor to stop the goods so long as they have not come into the actual possession of the vendee. The right to stop *in transitu* is not allowed to a vender unless in case of the bankruptcy of the vendee or his stoppage of payment. This general rule is in reality an extension of the right of lien, and is a remedial right of a vender. The *stoppage in transitu* does not do away with the sale, nor does the seller reacquire absolute ownership in the property. If, after the return of the property to the hands of the vender, the vendee demand that the contract be carried out he may enforce such demand. It is not necessary that the insolvency should occur *after* the sale; if, at the time of the bargain the vendee was in fact insolvent and the vender was ignorant of that fact, the right of stoppage accrues. The power may be exercised so long and only so long as the goods remain within the custody of middlemen employed to complete the transit, or agents of the vender. When the goods come within the custody of the vendee or his agent, the vender comes into the position of any other creditor. It has been held that where coal was delivered by a railroad company on a wharf belonging to itself, but of which it had been accustomed to allow the vendee the sole use (without consideration) the control of the corporation had ceased, and the right of stoppage *in transitu* no longer existed. So where the goods are stored in a bonded warehouse and the usual bonds are given by the vendee, the vender's right no longer exists. If the consignee have assigned the *bill of lading* regularly indorsed and forwarded by the consignor, the bill is now regarded as a *quasi* negotiable instrument; and it seems well established that the right of stoppage is destroyed by the assignment. The method of exercising the right is by notice to the middleman or common carrier, forbidding him to deliver the goods to the vender, and demanding their return. If this be disregarded a right of action accrues to the vender as against the middleman, separate from his right to recover the goods, from the vendee or his assignee. The right of recovery is subject to the common carrier's lien.

STOPPAGES, MILITARY AND NAVAL, in Eng. are deductions made from the pay of officers and men, in consideration of supplies made to them, or in aid of certain institutions. These stoppages were formerly more numerous than now. Thus, every officer and man had to pay toward Chelsea and Greenwich hospitals, and a soldier had to pay for his kit by a stoppage from the bounty. These stoppages have been remitted. Those now remaining are, under ordinary circumstances, limited in the navy to payment for slops (i.e., clothing) issued to men, or for willful damage: in the army, for forage, 8d. each ration by cavalry officers, and 6d. for artillery officers (though their horses eat the same); for messing on board ship; for diet in hospital, if sick through the man's own fault; for cost while in prison; for damages to barracks; and as a fine.

STORAGE BATTERIES. See **ELECTRIC MOTORS**; **MAGNETO-ELECTRIC MACHINES**.

STORAX, a fragrant resinous substance, the *styrax* of the ancients, obtained from the storax tree (*styrax officinalis*), a native of the countries around the Mediterranean sea, and belonging to the natural order *styracaceæ*, an order of exogenous plants, containing more than 100 known species. The species of this order are found in the tropical and sub-tropical parts of Asia, extending also into Europe and Africa, and the warm parts of America. *Styrax officinalis*, which produces storax, is a tree of 15 to 20 ft. high, a native of the Levant. Storax is obtained by wounding the bark, when it exudes and hardens in the air. It appears in the form of reddish-yellow tears about the size of a pea, opaque, soft, and adhesive; or in dry brittle masses, wrapped in the leaves of a kind of reed, when it is called *S. calamita*. Storax has a fragrant odor and an aromatic taste, and is stimulating and expectorant. It was formerly much more in use in medicine than now.

Benzoïn (q. v.) is the produce of a species of *styrax*. The *liquid storax* of the shops is doubtfully regarded either as produced by *styrax officinalis*, or by a species of *liquidambar* (q. v.). It seems probable that there are two kinds.

STOREY, a co. in w. Nevada, drained by the Carson and Truckee rivers, traversed by the Southern Pacific and the Virginia and Truckee railroads; about 270 sq. m.; pop. '90, 8806. The surface is mountainous. The soil is poor. The gold and silver mines of this county are very rich, including the great Comstock lode. Co. seat, Virginia City.

STOREY, WILBUR FISK, b. Vt., 1819; entered the printing business in which he served an apprenticeship, and went to New York, where he obtained a position in the office of the *Journal of Commerce*. He removed to Laporte, and afterward to Mishawaka, Ind.; the first in 1838, the second three years later; in both towns attempting to establish a democratic weekly newspaper, but without success. In 1842 he made a similar venture at Jackson, Mich.; and in 1854 bought the *Detroit Free Press*, which he conducted until 1861, when he bought the *Chicago Times*. The latter paper he succeeded in establishing on a firm basis, making it one of the most successful papers in the west. He d. 1884.

STORK, *Ciconia*, a genus of birds of the same family (*ardeidæ*) with herons and bitterns; large birds; with long legs, four-toed, the three front toes webbed to the first joint; the tail short; the wings large; the bill longer than the head, straight, strong, pointed, and without any groove, the nostrils pierced longitudinally in the horny substance; the eyes surrounded by naked skin. The species are not numerous, but they are of very wide geographic distribution. The COMMON STORK, or WHITE STORK (*C. alba*), is a native of the greater part of the Old World, a migratory bird, its range extending even to the northern parts of Scandinavia. It is common in most parts of Europe. It is about 3½ ft. in length. The head, neck, and whole body are pure white; the wings partly black; the bill and legs red. The neck is long, and generally carried in an arched form; the feathers of the breast are long and pendulous, and the bird often has its bill half hidden among them. The stork frequents marshy places, feeding on eels and other fishes, batrachians, reptiles, young birds, and small mammals. It makes a rude nest of sticks, reeds, etc., on the tops of tall trees, or of ruins, spires, or houses. In many parts of Europe, especially in Holland, it is a very common practice to place boxes for storks, and it is considered a fortunate thing for a household that the box on the roof is occupied. Storks are protected by law in some countries, on account of their good services not only in destroying reptiles and other troublesome animals, but in the removal of offal from the streets of towns, in which they stalk about with perfect confidence, even in the midst of throngs of people. They have been celebrated from ancient times for the affection which they display toward their young; and have also had the reputation—not so well founded—of showing great regard to their aged parents. Before they take their departure from their summer haunts, they congregate in large flocks, which make a great noise by the clattering of their mandibles, and are popularly regarded as holding consultation. The stork has no voice. Its flight is powerful, and very high in the air. It has ever been a very rare bird in Britain. The flesh of the stork is rank, and not fit for food. See illustration, BIRDS, vol. II., fig. 21.—Another species, the BLACK STORK (*C. nigra*), rather smaller, the plumage of the upper parts glossy black, the under parts white, is also common in many parts of Europe, Asia, and Africa.—The SOUTH AMERICAN STORK (*C. maguari*) is very similar to the common stork.

STORMONT, a co. in e. Ontario, having the St. Lawrence river for its s. boundary; drained in the n.w. by the Little Nation river; 260 sq.m.; pop. '91, 27,156. It is traversed on the St. Lawrence shore by the Grand Trunk railway. The surface is uneven, diversified by small streams, and thinly timbered, except in the neighborhood of the water-courses. Co. seat, Cornwall.

STORMS are violent commotions of the atmosphere, occurring in all climates, particularly in the tropics, and differing from other atmospheric disturbances in the extent over which they spread themselves, their destructive power, and the sudden changes which take place in the direction of the wind. There is, perhaps, no question in science in which there has been so large an admixture of speculation with fact, as in the attempts made to reduce the phenomena attendant on storms under general laws; the reason being, that meteorological observatories were too few in number, and too wide apart, to enable any one to give the barometer pressure, the general course of the winds, and the rainfall, without drawing largely on conjecture. Now, however, owing to the growing popularity of meteorology, and the countenance happily given to it by most civilized nations, sufficient data may be obtained for a fuller and more satisfactory statement of the facts. See METEOROLOGY: SIGNAL SERVICE OF THE U. S.: WEATHER.

We subjoin two charts of Europe, showing, from actual observations made at upward of 100 localities scattered over that continent, the barometric pressure, and direction and force of the wind, at 8 A.M. of the 1st and 2d of Nov., 1863, during part of the course of two storms which passed over Europe at that time. The isobarometric lines, or lines showing where, at the above hours, the height of the barometer was the same, are given for every two-tenths in the difference of the pressure. Hence, where these lines approach near each other, or crowd together, the difference of pressure, or the atmospheric distur-

ance, was the greatest; and the least where they are most apart—a distinction of the utmost importance in determining where the storm may be expected to rage in greatest fury. The arrows show the direction of the wind, being represented flying with it. The force of the wind is shown (1) by plain arrows, which represent light and moderate winds; (2) by arrows feathered on one side only, which represent high winds; (3) by arrows feathered on both sides, which represent strong gales, storms, or hurricanes.

The mean atmospheric pressure, at the level of the sea, may be stated to be 29.9 inches. When, therefore, the barometer falls below 29.9, the equilibrium of the atmosphere is more or less destroyed, according to the amount of the fall, and it is within this *area of low barometer* that a storm may be expected to occur. Hence, while we trace these low pressures, as they advance over the earth's surface from day to day, we trace at the same time the progress of the storms.

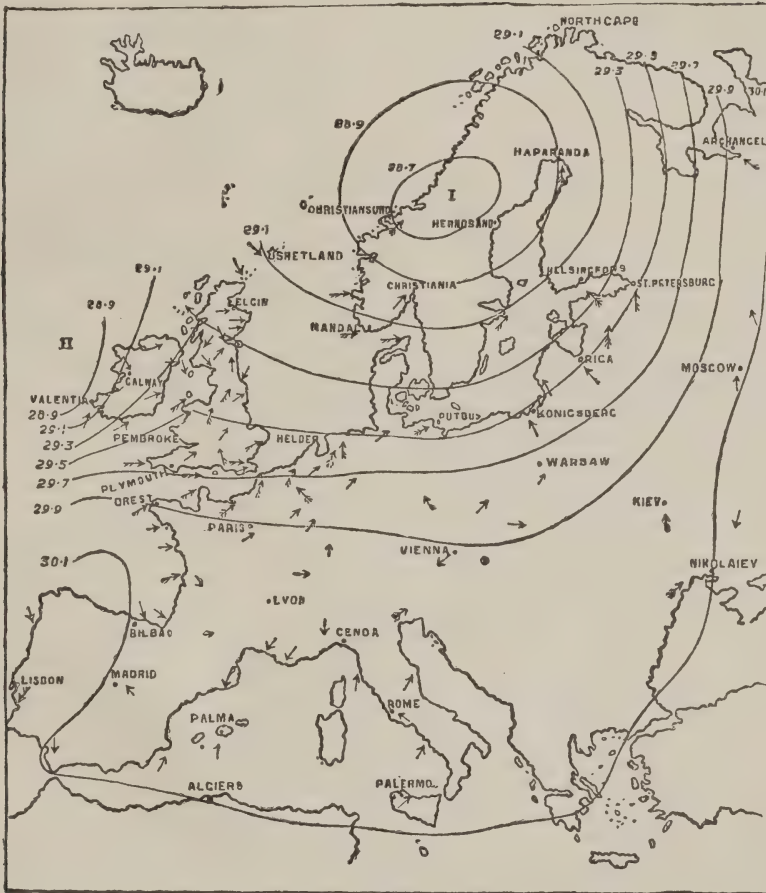

FIG. 1.—At 8 A.M., Nov. 1, 1863.

Form and Extent of Storm Areas.—The circular isobarometric lines on the charts represent very accurately the general shape storms assume. The area of almost every storm is either circular or slightly elliptical, and when elliptical, the major axis of the ellipse seldom exceeds twice the length of the minor axis. Rarely in Europe, but in America less rarely, the form of storms is much more elongated. The outline is occasionally very irregular, but in all such cases the storm will be found to have parted into two or more distinct storms, which remain separate for some time and then reunite. This circular form of storms, which an examination of some hundreds, especially in Europe, has shown to be their general characteristic, is a most important feature, whether as determining the practical rules for the guidance of sailors in storms, or for the forecasting of storms at particular sea-ports, in respect of the direction from which they may be expected to come, and the veerings of the winds during their continuance. The extent over which storms spread themselves is very variable, being seldom less than 600 miles in diameter, but

often two or three times that amount, or even more. Almost the whole of Europe is sometimes overspread by a single storm at one time. The area of storms is by no means constant from day to day, but varies in size, sometimes expanding and sometimes contracting. And it is worthy of remark that when a storm contracts its area, the central depression gives signs of filling up, and the storm of dying out. On the other hand, when it increases in extent, the central depression becomes deeper, the storm increases in violence, and occasionally is broken up into two, or even three, depressions, which become separate storms, with the wind circling round each.

Direction in which Storms advance.—It may be premised that by the direction of a storm is meant, not the direction of the wind, but the path followed by the center of disturbance. The direction in which their progressive motion takes place differs in different parts of the world, being probably determined by the prevailing winds. See WIND. Thus, about half the storms of middle and northern Europe travel from the s. w. toward the

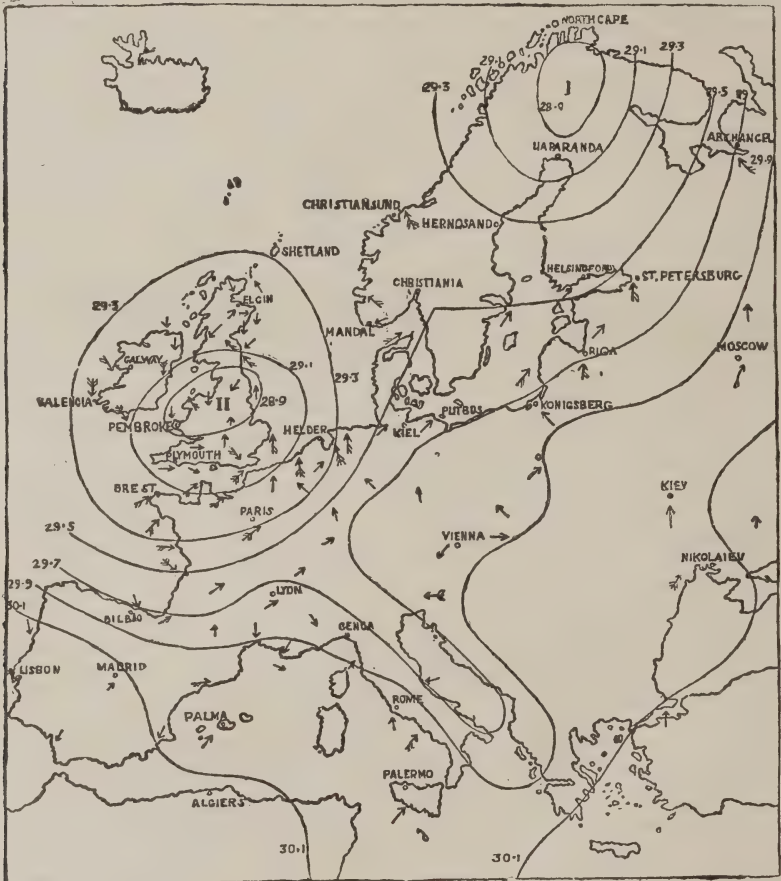

FIG. 2.—At 8 A.M., Nov. 2, 1863.

n.e., and 19 out of every 20, at least, travel toward some point in the quadrant from the n.e. to the s.e. Observation shows that the longer axis of the storm is almost always coincident with the direction in which the storm appears to be moving at the time. Storms do not always proceed in the same uniform direction from day to day, and though the change which occurs in the direction of their progressive motion is generally small, yet occasionally it is very great. Thus, of the many interesting features peculiar to the storm which passed over Europe in the beginning of Dec., 1863, none were more remarkable than the sudden changes of its progressive motion. It was first observed on the w. of Ireland, from which it advanced e. to Liverpool, then turned s. through Worcester and Oxford to Cherbourg in France; it thence retreated n. through Oxford to Shields, from which it proceeded e. to Copenhagen. By the time it arrived at Copenhagen its extent was only a fourth of what it had been the previous day, and the central depression half an inch less. Twelve hours later, the atmospheric equilibrium was restored, the storm having died out on reaching the Baltic sea. The storms of the Med-

iterranean follow a different course. Many of them proceed from the n. to the s., influenced probably by the heated air rising from the Sahara; a considerable number proceed from the e., and pass to the westward over Greece and Italy to the Alps; while very few are observed to travel in an easterly direction. By far the greater number of the storms of North America take their rise in the vast plain which lies immediately to the e. of the Rocky mountains, and thence advance in an eastern direction over the United States; some of them, crossing the Atlantic, burst on the western shores of Europe. But the relation of the American to the European storms is not well established, nor will be till observation has collected more facts, and discussion has sifted their significance. If once the connection be fully established, the system of forecasting storms to European ports will become much more certain and complete than it is at present. The storms of the West Indies generally take their rise from near the region of calms, and tracing out a parabolic course, proceed first toward the n.w., and then turn to the n.e. about 30° n. lat., many of them traversing the e. coasts of North America as far as Nova Scotia. South of the equator they follow an opposite course. Thus, in the south Atlantic and Indian ocean they first proceed toward the s.w., and then gradually curve round to the s.e. The hurricanes of Hindustan usually pursue a parabolic path, first traversing the eastern coast toward Calcutta, and then turning to the n.w. up the valley of the Ganges. The typhoons of the Chinese seas resemble, in the course they take, the hurricanes of the West Indies. Observations are wanting from other parts of the world to determine the course of storms.

Probably the course tracked out by storms is determined by the general system of winds which prevail, modified by the unequal distribution of land and water on the surface of the globe. Facts seem at present to point to this general conclusion, viz., *Storms follow the course of the atmospheric current in which the condensation of the vapor into the rain which accompanies them takes place.*

Rate at which Storms travel.—If the position of the center of Storm I. on Nov. 2 be compared with its position on the 1st on the charts, it will be found to have traveled 420 m. in 24 hours, or at the rate of $17\frac{1}{2}$ m. an hour. Similarly Storm II. will be found to have traveled in the same time 400 m., or at the rate of $16\frac{2}{3}$ m. an hour. This is about the average rate of the progressive movement of European storms. Sometimes, however, it falls as low as 15 m. an hour, and sometimes increases to 30 m. an hour. Within the tropics the onward motion of storms sometimes rises to 40 m. an hour.

Relations of Temperature, Rain, and Cloud to Storms.—The temperature increases a few degrees at places toward which and over which the front part of the storm is advancing, and falls at those places over which the front part of the storm has already passed. In other words, the temperature rises as the barometer falls, and falls as the barometer rises. When the barometer has been falling for some time clouds begin to overspread the sky, and rain to fall at intervals; and, as the central depression approaches, the rain becomes more general, heavy, and continuous. After the center of the storm has passed, or when the barometer has begun to rise, the rain becomes less heavy, falling more in showers than continuously; the clouds break up, and fine weather ushered in with cold breezes ultimately prevails. It should be here remarked that, if the temperature begins to rise soon and markedly after the storm has passed, a second storm may be expected shortly. The rainfall is generally proportioned to the suddenness and extent of the barometric depression at the place where it falls.

Observations of the Wind.—First as to the direction of the wind. If the winds in Storm II. on Nov. 2 be attentively examined they will be observed whirling round the area of low barometer in a circular manner, and in a direction contrary to the motion of the hands of a watch, with—and be this particularly noted—a constant tendency to turn inward toward the center of lowest barometer. The wind in storms neither blows round the center of lowest pressure in circles, nor does it blow directly toward that center, but takes a direction nearly intermediate, approaching, however, nearer to the direction and course of the circular curves than of the radii to the center. The greater the force of the wind is at any place it will be observed to approach the more nearly the direction here indicated. And where the direction of the wind differs to any material degree from this general law, it is light, and consequently more under local influences, which turn it from its course. Thus, the center of the storm being near Liverpool, the direction of the wind is s.w. at Paris, s. at Yarmouth, n.e. at Silloth, n. at Dublin, and n.w. at Cork—instead of s. at Paris, s.e. at Yarmouth, n. at Silloth, n.w. at Dublin, and w. at Cork, if it had blown directly to the area of lowest pressure; and w. at Paris, s.w. at Yarmouth, e. at Silloth, n.e. at Dublin, and n. at Cork, if it had circulated in the direction of the isobarometric curves. Hence in this storm the winds circulate round the center of least pressure, or, to speak more accurately, the whole atmospheric system flows in upon the center in a spiral course. This rotatory peculiarity is common to all storms in the northern hemisphere that have yet been examined. In the southern hemisphere, a rotatory motion is also observed round the center of storms, but it takes place in a contrary direction, or in the direction of the motion of the hands of a watch, instead of contrary to that direction, as obtains n. of the equator.

Prof. Taylor has the merit of having first applied Duvé's law of rotation to explain the direction of the rotation of storms round their center. This may be explained by referring to Storm II. on Nov. 2. On that morning, the pressure over England being

much less than in surrounding countries, if the earth had been at rest, air-currents would have flowed from all directions to England, to fill up the deficiency, in straight lines. The earth, however, is not at rest, but revolves from w. to e.; and as the velocity of rotation diminishes as the latitude increases, it is evident that the current which set out, say from Lyon to the n., would, on account of its greater initial velocity when it arrived at Paris, blow no longer directly to the n., but to a point a little to the e. of n.; in other words, it would no longer be a s., but a s.w. wind. Again, since the current from the n. of Scotland had a less velocity than those parts of the earth's surface on which it advanced, it lagged behind, and consequently, by the time it arrived at Silloth in the n. of England, had changed from a n. to a n.e. wind. Similarly the n.w. current changed to a n., the s.w. to a w., etc. The w. and e. currents, since they continued in the same latitude, would have blown in the same direction, if they had not been disturbed by contiguous currents. Hence in a storm the whole system of winds rotates round the center. As a further confirmation of the truth of this theory, it is observed that when a high barometric pressure covers a limited space the wind is always observed gently *whirling out of this area of high barometer*, but in exactly opposite directions in both hemispheres from those assumed when it blows round and in upon an area of low pressure. It follows in the northern hemisphere that, as storms advance, the general veering of the wind at places lying n. of the path of their center is from n.e. by n. to w.; and at places s. of their center from n.e. by e. and s. to n.w., and conversely in the southern hemisphere.

Next, as to the force of the wind: The rule is simple, and without exception—viz., the wind blows from a high to a low barometer, and with a force proportioned to the difference of the barometric pressures. Hence, where the isobarometric lines crowd together, the violence of the storm is most felt, and where they are far asunder, the winds are moderate and light. We thus see the importance of observations from a distance in forecasting the weather. To take an illustration: the importance of observations from Norway and Sweden to all sea-ports on the e. coast of Great Britain cannot be overestimated. For if the pressure be high in Norway and low in Great Britain, violent easterly gales will sweep down on North Britain, and, unless foreseen and provided against, strew the coast with wrecks; whereas, if the pressures be nearly equal, little danger need be apprehended, even though the barometer be low in Britain. As the wind nears the center of the storm it gradually abates, till on reaching the center a lull or calm follows. Calms and light winds also prevail along the ridge of highest barometer, or the region where the pressure is greatest, and on receding from which the pressure diminishes on each side. It may not inaptly be compared to the water-shed in physical geography, since from it the wind flows away toward the places where the pressure is less.

We have stated that the progressive motion of storms varies from 15 to 40 m. per hour, which measures the time taken in passing from one place to another, but it gives no indication of the violence of the storm. This is determined by the rotatory velocity of the wind round the center of the storm, which in Europe and America frequently amounts to 60 or 80 m. an hour continuously for some time. In intermittent gusts, a speed of 120 m. an hour has been several times observed in this country—a velocity which is perhaps sometimes surpassed by storms within the tropics.

Of the different theories hitherto proposed, we need only refer to the rotatory and the centripetal theories. The rotatory, or, as it is commonly called, the cyclonic theory, was first proposed by Piddington, and has since been elaborated by Redfield, Reid, Dové, and others. By this theory storms are considered as revolving round an axis either upright or inclined to the horizon, while at the same time the body of the storm has a progressive motion over the surface of the globe; the barometric depression, as caused by the centrifugal force, driving the air from the center to the circumference of the storm. Dové, certainly the ablest advocate of this theory, holds that cyclones are formed when two atmospheric currents, the equatorial and polar, flow side by side, they being, as it were, the eddies formed at the line of junction. To this theory several objections may be urged. Observations from the numerous observatories recently established in Europe and America, in no case exhibit a true cyclonic movement of the winds round the center of the storm; that is, they do not rotate in circles returning on themselves, even when the barometric depression is deepening and the storm expanding, but invariably exhibit, along with the rotatory motion, a constant tendency to blow in upon the center of the lowest pressure. Hence it is clear that the barometric depression is not caused by the centrifugal force of the storm. The same may be shown from theory; for though the wind were to blow round a circle 400 m. in diameter at the rate of 70 m. an hour, the centrifugal force would depress the barometer at the center only $\frac{1}{800}$ in.; whereas half an inch, or even a whole inch of depression often occurs. Again, if cyclones arose from the flowing of the polar and equatorial currents side by side, the rotatory motion would not always be in one direction, but would be determined by the relative position and strength of the two currents. The whole facts of the rotation of the wind are explained when it is considered as caused by air currents flowing toward a low barometer along the globular surface of the earth rotating eastward.

The rotatory character of storms has been denied by Espy, who maintains that the wind blows from every quarter toward the center of the storm, and that the central depression is

caused by the development of heat which occurs whenever the vapor of the atmosphere is condensed into cloud or rain; the heat thus developed rarefying the surrounding air, and causing an upward current. The most valuable part of this theory lies in directing the attention of meteorologists to the heat of condensation, which must play an important part in the movements of the atmosphere. It is, however, insufficient, since it leaves some important points unexplained. Thus, more heat being set free when vapor is converted into snow than rain, a greater depression ought to follow a fall of snow than of rain, which is not found to be the case; it also leaves unexplained the appearance of high pressures, sometimes suddenly appearing on the scene, and seeming to divert the storm from its course, or drive it before them. But the weak point of this theory is the centripetal direction of the winds. Espy worked from imperfect data, and never being able to lay down the isobarometric lines, he could only guess at the true center of the storm; and further, he was misled by a peculiar characteristic of American storms, which being generally in the form of rather elongated ellipses moving *eastward*, many of the winds blow directly to the center, or nearly so.

STORNOWAY. See LEWIS WITH-HARRIS.

STORRES, CHARLES BACKUS, 1794-1833; b. Mass.; studied at Princeton college, but prevented by ill-health from graduating; graduated at Andover theological seminary, 1820; went to South Carolina and was ordained, 1821, by the Charleston Congregational association; settled at Ravenna, Ohio, 1822-28; elected professor of divinity in Western Reserve college, 1828, and president, 1831.

STORRES, RICHARD SALTER, D.D., LL.D., 1787-1873; b. Mass.; studied at Yale college, 1802-03; taught in Clinton academy, East Hampton, L. I., 1804-06; graduated at Williams college, 1807; studied theology a year at Andover, ordained pastor of the First church (Congregational) at Braintree, Mass., 1811, where he preached 62 years. He published *Memoir of Rev. Samuel Green*; a *Discourse on the Fiftieth Anniversary of his Ordination*; and 20 single sermons. He edited the *Boston Recorder*, was co-editor of the *Congregationalist*, and contributed to the *Panoplist*, *Home Monthly*, etc. He had wide repute as a vigorous thinker and preacher.

STORRES, RICHARD SALTER, D.D., LL.D., b. Mass., 1821; graduated at Amherst college, 1839, and Andover theological seminary, 1845; was ordained pastor of the Harvard Congregational church, Brookline, Mass., the same year; pastor of the church of the Pilgrims, Brooklyn, N. Y., 1846. He was co-editor of the *Independent*, 1848-61. He has published *Graham Lectures on the Wisdom, Power, and Goodness of God as Manifested in the Constitution of the Human Soul*; lectures on *The Conditions of Success in Preaching Without Notes*; *Life and Letters of the Rev. Daniel Temple*; *Report on the Revision of the English Version of the Bible, undertaken by the American Bible Society*; *Six Lectures Delivered at the Brooklyn Institute*; *Annual Address before the Society of Inquiry, Union Theological Seminary, New York*; *Early American Spirit and the Genesis of it*; *John Wycliffe and the First English Bible*; *Manliness in the Scholar*; *Psalter, with form of Service adopted by the Church of the Pilgrims*; *Recognition of the Supernatural in Letters and in Life*; and many occasional discourses, sermons, and orations. He ranks among the foremost pulpit orators in America, being unsurpassed for rhetorical magnificence and affluent and splendid diction in unwritten address.

STORRES, WILLIAM LUCIUS, LL.D., 1795-1861; b. Middletown, Conn.; brother of H. R. Storrs. He graduated at Yale college, 1814; studied law at Whitestown, N. Y.; admitted to the bar, 1817; resided in Middletown; member congress, 1829-33, and 1839-40. In the latter year he was appointed associate judge of the state supreme court of errors; chief-justice, 1856; professor of law in Yale college, 1846-47. His decisions are printed in the *Connecticut Reports*.

STORTHING (from *stor*, great, and *thing*, court), the legislative assembly of Norway (q.v.).

STORY, a co. in central Iowa, drained by Montgomery and Indian creeks and the Skunk river; traversed by several branches of the Chicago and Northwestern railroads; 576 sq. m.; pop. '90, 18,127, chiefly of American birth. The surface is rolling. The soil is fertile. The principal productions are corn, wheat, oats, and hay. Co. seat, Nevada.

STORY, JOSEPH, an American jurist and judge, was b. at Marblehead, Mass., Sept. 18, 1779; was educated at Harvard college, and, though admitted to the bar in 1801, gave his attention chiefly to general literature and poetry. Having published a volume in 1804, *The Power of Solitude*, and other poems, which met with no success, he bade farewell to the muses, and devoted himself to law and politics. Elected to the state legislature in 1803, he became a leader of the republican, or, as it was afterward called, the democratic party, and defended the measures of Jefferson. In 1808 he was elected to congress, where he gave a moderate support to the war measures of Mr. Madison, who, however, in 1811, appointed him associate justice of the supreme court of the United States, a place he filled with great credit for 34 years. In 1820, as a member of the Massachusetts constitutional convention, he advocated a property basis for the senate. In 1829 he became law professor at Harvard. His later politics were of the federalist school of Washington and Hamilton, and these tincture his *Commentary on the Constitution of the United States*. His *Conflict of Laws*, and other legal treatises, have passed

through many editions. His legal writings and decisions are among those oftenest quoted in the higher courts of law. He died Sept. 10, 1845.—In 1854 appeared Story's *Miscellaneous Writings*; and in 1851 a life of him by his son William Wetmore Story.

STORY, ROBERT HERBERT, b. at Rosneath, Dumbartonshire, Scotland, Jan. 28, 1835. Studied at the universities of Edinburgh, St. Andrew's, and Heidelberg; was appointed assistant minister of St. Andrew's Church, Montreal, Canada, 1859; succeeded his father as minister of Rosneath, 1860-87. Since 1887 he has held the chair of church history in the university of Glasgow; has edited the *Scottish Church* since it was founded in 1885, since 1894 has been moderator of general assembly, and has been one of H. M.'s chaplains since 1886. Among his publications are *Robert Story of Rosneath, a Memoir* (London, 1862), *Christ the Consoler* (Edinburgh, 1865), *Life and Remains of Robert Lee, D.D.* (London, 1870), *William Carstairs* (1874), *Creed and Conduct, Sermons* (1878), *Health Haunts in the Riviera* (Paisley, 1881), and *Nugæ Ecclesiasticæ* (Edinburgh, 1884).

STORY, WILLIAM WETMORE, b. Mass., 1819; son of Joseph; educated at Harvard college, and admitted to the bar. After the publication of several legal treatises he devoted himself to literature and sculpture. In 1848, he removed to Rome, Italy, where he has since resided. Among his sculptures are the marble statue of his father at the chapel of Mt. Auburn cemetery, statues of Edward Everett and Josiah Quincy, busts of Theodore Parker and James Russell Lowell, and many ideal works and groups, including a "Semiramis," a "Sibyl," a "Sappho," a "Cleopatra," and "Jerusalem." Among his prose writings are *Life and Letters of Joseph Story* (1851); *Roba di Roma* (1862); *Proportions of the Human Figure* (1866). Among his works in verse are *Poems* (1856); *Graffiti d'Italia* (1869); *The Roman Lawyer in Jerusalem* (1870); *Tragedy of Nero* (1875); *Stephanie* (1877); *Fiametta and Poems* (1886); *Conversations in a Studio; Excursions in Art and Letters* (1891). He d. 1895.

STOSCH, ALBRECHT VON, b. Prussia, 1818; received a military education, and was commissioned lieut. in 1835; displayed great proficiency in the technical and economical branches of the service; rose in rank and became tutor of the crown prince. In 1866 he was appointed director of the economy department in the war ministry, and in the war with France, 1870-71, was superintendent of the Prussian commissary department, and chief of staff in the army left in France after the conclusion of peace. In 1872 he was appointed chief of the naval department, then first separated from the army; and in 1875 received the title of admiral.

STOTHARD, THOMAS, R.A., an eminent designer and painter, was the son of a London publican, who kept the *Black Horse* in Long Acre, and was b. there in 1755. He received a respectable education in different boarding-schools, and on his father's death, having shown a predilection for the use of the pencil, was bound apprentice to a pattern-drawer in the city, but was released from his engagement before the term of expiry, and betook himself to more artistic work. His first notable effort was a series of designs for the *Town and Country Magazine*, which was followed by his imaginative compositions for Bell's *British Poets* and the *Novelist's Magazine*. The popularity of these was so great that for many years his services were constantly in request by the leading publishers in London. His earliest pictures exhibited at the royal academy were "The Holy Family," and "Ajax defending the Body of Patroclus." In 1791 he was chosen an associate, in 1794 a member, and in 1813 librarian of the academy. He died April 27, 1834. Stothard was really an admirable and facile illustrator. Not less than 3,000 of his designs are known; but his paintings, although gracefully enough "composed" and finely colored, are destitute of the originality that comes from a study of nature, and painfully resemble enlarged "illustrations" for books. Perhaps the best known and the most agreeable of the set is his "Canterbury Pilgrims," engraved in 1817; others are the "Flecht of Bacon," the "Fête Champêtre," and the paintings executed for the staircase at Burreigh, the seat of the marquis of Exeter. See Mrs. Bray's *Life of Thomas Stothard, R.A., with numerous Illustrations from his Works* (1851).—His son, **CHARLES ALFRED STOTHARD** (b. 1786, d. 1821), was an antiquarian draughtsman.

STOUGHTON, a town in Norfolk co., Mass.; on the New York, New Haven, and Hartford railroad; 18 miles s. of Boston. It was incorporated in 1726; contains the villages of Stoughton, North Stoughton, West Stoughton, Belcher's Corner, and Dry Pond; and has a public library, public park, electric lights, electric street railroad, and manufactories of shoes, hosiery, leather, and woolen and rubber goods. Pop. '90, 4852.

STOUGHTON, EDWIN W., LL.D., b. Vt., 1818; studied law in New York city and was admitted to the bar in 1840. He soon acquired an extensive practice in the metropolis, especially in patent cases. In the argument before the electoral commission following the presidential election of 1876, he was counsel for the republican side. In 1877 he was made U. S. minister to Russia by President Hayes, and returned in 1879. D. 1882.

STOUGHTON, ISRAEL, about 1580-1645; b. England; one of the first settlers of Dorchester, Mass., and member of the first general court, 1634. He was disabled from holding office for publicly denying the powers of the governor in certain matters. He commanded the expedition of 1637 against the Pequots, was in 1641 a commissioner to carry on the government of New Hampshire, and was governor's assistant, 1637-42, and in 1644. In the last year he returned to England and became an officer in the army.

STOUGHTON, WILLIAM, 1632-1701; b. England; graduated at Harvard in 1650. In 1650 he went to England; was a fellow of New college, Oxford; lost his fellowship at the restoration and returned to Massachusetts in 1662. He was agent in England for the colony, 1677-79, and was elected governor 1689, but refused the office. He was a member of the council of sir Edmund Andros, 1686-89, when he joined the council of safety which deposed Andros. In 1662 he was lieut.-gov., and the same year was appointed chief-justice of Massachusetts. Stoughton hall at Harvard college is named after him.

STOUGHTON, WILLIAM L., b. N. Y., 1827; studied law and practiced in Sturges, Michigan. In 1861 he was U. S. district attorney. He became col. of a Michigan regiment, and fought with distinction at Stone river, Chickamauga, and Atlanta, losing a leg at the last place. He attained the rank of brev. maj.gen. of volunteers, and at the close of the war became attorney-general of Michigan; in congress, 1869-73.

STOURBRIDGE, a market-t. in the co. of Worcester, and 20 m. n.e. of the town of that name, on the left bank of the Stour. It contains iron-works and glass, earthenware, and fire-brick factories. "Stourbridge clay," upon which the action of fire has less effect than upon most varieties of clay, is an article of export. Glass-house pots, crucibles, etc., are made of it. Pop. '91, 9386.

STOUTHRIEFF, in the law of Scotland, means robbery committed in a dwelling-house.

STOVE, a fireplace in which the fire is generally quite shut in. The term is also applied to a room or closet heated for the purpose of drying and other operations, and to hot-houses, in which the artificial heat is constantly maintained at a high temperature. Stoves for domestic purposes will be noticed under the head of **WARMING AND VENTILATION**. Particular kinds of hot-house stoves are already noticed in the articles **BARK-STOVE** and **DRY STOVE**. Stoves are also used for *forcing* fruits, so as to procure them in winter or spring. In the management of stoves, the general rule is that the temperature must never be allowed to fall below 60° Fahr. The free access of air is, of course, desirable, but the windows are not opened unless the temperature reaches 70° Fahr., and care must be taken that cold blasts do not enter, which are often very injurious.

STOW, or **STOKE** (A.-S. *stoc*, a stockaded place), a component element of many names of places, as Bristow or Bristol, Stockholm.

STOW, BARON, D.D., 1801-69; b. N. H.; graduated Columbian college, D. C., 1825; ordained pastor of a Baptist church, Portsmouth, N. H., 1827; pastor of Baldwin-place church, Boston, 1832, and of Rowe street church, 1848-67. He published *Daily Manna for Christian Pilgrims*; *Christian Brotherhood*; *The Whole Family in Heaven and Earth*; *Memoir of Harriet Dow*; *History of the Danish Missions on the Coast of Coromandel*; *History of the English Baptist Mission to India*; *First Things*; *Helon's Pilgrimage*; *Missionary Enterprise*. He edited *Columbian Star*, 1825-27; was recording secretary of missionary conventions, 1838-46.

STOW, JOHN, one of the earliest and most diligent collectors of English antiquities, was b. in London in the year 1525. He was brought up to his father's trade of a tailor in Cornhill, but ultimately abandoned it for antiquarian pursuits. Writing in 1575, he says: "It is now ten years since I, seeing the confused order of our late English chronicles, and the ignorant handling of ancient affairs, leaving mine own peculiar gains, consecrated myself to the search of our famous antiquities." A patriotic sacrifice, which ought to have insured to the devoted antiquary from his king and country an old age of ease and honor, but which only brought him to want and beggary! In his 79th year, Stow obtained letters-patent from James I. authorizing him to become a mendicant, or, as it is expressed in the state document, "to collect amongst our loving subjects their voluntary contributions and kind gratuities." He died April 5, 1604, and was buried in the parish church of St. Andrew Undershaft, in Aldgate ward, where his monument of terra-cotta, erected at the expense of his widow, may still be seen. The principal works of Stow are his *Summary of English Chronicles*, first published in 1561, and subsequently reprinted every two or three years, with a continuation to the date of each new publication; *Annals of England*, 1580, and reprinted in 1592, to which year the annals are brought down; and *A Survey of London*, the most important of his writings, published in 1598. Besides these original works, Stow assisted in the continuation of Holinshed's Chronicle, Speght's edition of Chaucer, Leland's *Collectanea*, etc. He had collected or transcribed a vast number of MSS., and much valuable information which might otherwise have perished; and in the use of his stores he was liberal to others, while as an original historian he was faithful and impartial.

STOWE, CALVIN ELLIS, D.D., b. Mass., 1802; graduated Bowdoin college, 1824; Andover theological seminary, 1828; assistant professor at Andover, and assistant editor of *Boston Recorder*, 1828-30; professor of languages at Dartmouth college, 1830-33; of Biblical literature, Lane theological seminary, 1833-50. In 1836 he visited Europe in behalf of Ohio, to examine the German public-school system, and on his return published a report on *Elementary Education in Europe*, and subsequently reports on *Education of Immigrants*; *The Course of Instruction in the Primary Schools of Prussia*; *Elementary Instruction in Prussia*; divinity professor in Bowdoin college, 1850-52; professor of

sacred literature in Andover, 1852-64. Among his works are *History of the Hebrew Commonwealth*, from the German of Jahn; *Lectures on the Sacred Poetry of the Hebrews* from the *Prælectiones* of Louth; *Introduction to the Criticism and Interpretation of the Bible*; *Origin and History of the Books of the Bible*. He published papers in *Spirit of the Pilgrims*, *Biblical Repository*, *Bibliotheca Sacra*, *Atlantic Monthly*. He d. 1886.

STOWE, HARRIET ELIZABETH BEECHER, American author; third daughter of the Rev. Lyman Beecher, D.D.; was b. at Litchfield, Conn., June 14, 1812. Though unrestrained in her fondness for fiction when a child, her mind was often occupied with serious subjects, and when in her twelfth year she wrote a composition on the question, "Can the immortality of the soul be proved by the light of nature?" In 1823 she entered her sister's school at Hartford, and at the age of 15 became an assistant teacher. She accompanied her father to Cincinnati, and in 1834 began her literary career by writing *A New England Story*, in competition for a prize of \$50. This was afterwards included in *The Mayflower*, a volume of stories showing keen insight into New England character. In 1836 she was married to Prof. Calvin E. Stowe, and while at Brunswick wrote *Uncle Tom's Cabin* for the *National Era*, an anti-slavery paper published in Washington, intending to limit it to a few numbers. When published (two volumes, Boston, 1852; new edition, 1879), its success was so great that four stereotype editions of over 300,000 copies were sold in 4 years; 35 English editions were published; the English reprints circulated 500,000 copies; 37 translations (European and Asiatic) were made; and the story was extensively dramatized. As the truthfulness of her statements was denied by the southern press, she pub. in reply *A Key to Uncle Tom's Cabin* (1853). Visiting Europe, 1853, she was received with marked distinction, and was presented with a petition for emancipation signed by over 1,000,000 women of Great Britain and Ireland. Her experiences during this visit were recorded in *Sunny Memories of Foreign Lands* (Boston, 1854), in the compilation of which her brother Charles aided. Another anti-slavery novel, *Dred, a Tale of the Dismal Swamp* (1856), was republished as *Nina Gordon* (1866), but since issued under the original title. Then followed, *The Minister's Wooing*, a story of New England life in the 18th century (1859); *The Pearl of Orr's Island* (1862); *Agnes of Sorrento* (1862); *Little Foxes* (1865); *The Chimney Corner* and *Men of Our Time* (1868); and *Lady Byron Vindicated* (1869), a reply to a book pub. by the countess Guiccioli. Mrs. S. was, 1868-70, joint editor of *Hearth and Home*. She also pub. *Old Town Folks* (1869); *Sam Lawson's Fireside Stories*, and *My Wife and I* (1872); *Paganuc People* (1878); *Religious Poems*, several minor works, the last of these in 1881, and aided her son in preparing a *Memoir* of Prof. Stowe. In 1864 her husband removed to Hartford, Conn., which then became her home, though several winters were passed in Florida. See *Life* by her son (1889), and by Mrs. James T. Fields (1897). She died July 1, 1896.

STOWELL, WILLIAM SCOTT, Baron, the eldest brother of lord Eldon (q. v.), was b. at Heworth, Durham, Oct. 17, 1745. He was educated at Newcastle; went to Oxford in 1761, and became a college tutor. In 1779 he took the degree of D.C.L., removed to London, was called to the bar (1780), and admitted to the faculty of advocates at doctors' commons. Dr. Johnson introduced him to the Literary club, and he became well known in the most intellectual society of London. As an advocate he at once obtained a large practice, and his promotion was rapid. In 1788 he was appointed judge in the consistory court, knighted, and nominated a privy councillor. In 1798 he became judge of the court of admiralty, the highest dignity to which he could attain in his own branch of the profession. Both as an ecclesiastical and admiralty judge he won high distinction. He wrote no systematic treatise or text-book, but his judgments were admirably reported, and supply the best evidence of his extensive legal learning, his sagacity, and his great literary ability. He is the highest English authority on ecclesiastical law and the law of nations, and his judgments—those especially relating to the rights of belligerents and neutrals—have been described as the most valuable contribution made by an English judge to general jurisprudence since the time of lord Mansfield. As a politician sir William Stowell was not remarkable. He represented Oxford in the house of commons for 20 years, but he took no part in the business of parliament, although like his brother he was a zealous supporter of the conservative party and the established church. At the coronation of George IV. he was raised to the peerage under the title of baron Stowell of Stowell park. In 1828 he retired from the bench, and in 1836 died.

STOW MARKET, a small market t. of Suffolk, on the Gipping, 12 m. n.w. of Ipswich. Iron, leather, paper, and gun-cotton are manufactured. The Gipping is navigable to Stowmarket. Pop. '91, 4339.

STRABANE, a market t. of the co. of Tyrone, Ireland, on the river Mourne, 130 m. n.w. from Dublin, with which it communicates by railway. It communicates with Londonderry, and thus with the sea, by canal and river. The chief industry is connected with the linen trade, and there is also a valuable fishery. Pop. '91, 5013.

STRABISMUS. See SQUINTING.

STRABO, an ancient geographer, b. at Amasea in Pontus, about the middle of the 1st c. B.C. By the mother's side he was of Greek descent, and also closely connected with the Mithridatidæ; of his father or his father's family nothing is known. How the name Strabo ("squint-eyed") must have originated is obvious, but whether any of the family were so called before him is uncertain. Strabo was well educated under the grammarians, Tyrannio of Amisus in Pontus, and Aristodemus of Nysa in Caria, and the phil-

osopher Xenarchus of Seleucia in Cilicia. He does not appear to have followed any professional calling, but to have spent his life in travel and study, from which it may safely be inferred that he was possessed of wealth, or at least of considerable means. He died some time after 21 A.D., but how long we have no evidence to show. Strabo's *Geography* is a work of great value, in those parts especially which record the results of his own extensive observation. "Westward," he says in a passage in the 2d book, "I have traveled from Armenia to the parts of Tyrrhenia adjacent to Sardinia; toward the south, from the Euxine to the borders of Ethiopia. And perhaps there is not one among those who have written geographies who has visited more places than I have between these limits." Yet it must not be supposed that he describes with equal accuracy or fullness all the countries of whose geography he treats. Some he seems to have visited hurriedly, or in passing elsewhere; others he knows like a native. For example, his accounts of Greece, particularly the Peloponnesus, are meager in the extreme, and of many of the obscurer regions he writes chiefly from hearsay. He makes copious use of his predecessors, Eratosthenes, Artemidorus, Polybius, Posidonius, Aristotle, Theopompus, Thucydides, Aristobulus, and many other writers now lost to us, but he strangely depreciates the authority of Herodotus, and quotes few Roman writers except Fabius Pictor, and Julius Cæsar. The *Geography* comprises 17 books, of which the first two are introductory, the next eight are devoted to Europe, the six following to Asia, and the last to Africa. The style is pure and simple. The *editio princeps* of Strabo appeared at Venice in 1516; the latest and best is that by Gustaf Kramer (Ber. 1844, *et seq.*).

STRACHEY, WILLIAM, b. England, 1585; secretary of the colony of Virginia, 1610-12. He was shipwrecked on the Bermuda islands in 1609 with sir T. Gates, Somers, and Newport. His *True Reportory of the Wracke and Redemption of Sir Thomas Gates, upon and from the Islands of Bermudas*, is supposed to have suggested to Shakespeare the storm in the *Tempest*, and the allusion to the "still vext Bermoothes." He collected *For the Colony in Virginia Britannia Lawes Divine, Morall, and Martiall* (1612;) and wrote a *Historie of Travaile into Virginia*.

STRADELLA, a city of northern Italy, 10 m. s.e. of Pavia. Pop. '81 (communal), 8540 inhabitants. A monument has recently been erected to the statesman Depretis, who died here in 1887. Stradella was formerly a fortified city, depending on the bishops of Pavia.

STRADELLA, ALESSANDRO, a Neapolitan musical composer, b. about 1645; he is famous both in respect of his influence on the music of that age and of the tragical history of his life and death. His works, which consist of numerous airs, duets, cantatas, madrigals, an oratorio, and an opera, contributed largely to form the taste of the succeeding composers, particularly Purcell, Clari, Steffani, and Alessandro Scarlatti. Stradella was renowned for his exquisite voice and polished manner; and when engaged in Venice, instructing a young lady of rank, who lived in a criminal intimacy with a noble Venetian, the musician and his pupil became mutually enamored, fled to Rome, and were married there. They were traced thither by two bravos in the employ of the Venetian, who discovered them in the church of San Giovanni Laterano, where Stradella was assisting at the performance of an oratorio of his own, and both assassins, it is said, were so captivated with his voice and strains, that they at once abandoned their object and betrayed to him the plot in which they had been engaged. Pursued by other bravos to Turin, Stradella was stabbed, but not mortally, when lodged in the palace and under the protection of the duchess of Savoy. Some years afterward, however (about 1681), he went to Genoa, in pursuance of an engagement to compose an opera, and the day after his arrival both he and his wife were mortally stabbed in their bedchamber by the emissaries of their unrelenting persecutor.

STRADIVARIUS, ANTONIO, 1644-1737; b. Cremona; was a pupil of Niccolò Amati, and at first reproduced violins in the style of his master. In 1686 he acquired his own peculiar style, which subsequent makers of violins have deemed a model. He produced violins, violas, and violoncellos. He also made some viols of 6 and 7 strings, mandolins, guitars, and lutes. One of his violins, *La Pucelle*, has been preserved under glass, and has never been touched by the bow. Another specimen, the *Dolphin*, so called from the veined wood of its back, is the best Stradivarius violin in existence, and formerly belonged to the marquis de la Rosa.

STRAFFORD, a co. in s.e. New Hampshire, adjoining Maine, watered by the Lamprey, Cocheco, Piscataqua, and Salmon rivers; traversed by several branches of the Boston and Maine railroad; about 376 sq. m.; pop. '90, 38,442, chiefly of American birth. The surface is irregular. The soil is not fertile. Hay, butter, and potatoes are principal productions. There is much water-power and manufacturing. Co. seat, Dover.

STRAFFORD, THOMAS WENTWORTH, Earl of, eldest son of sir W. Wentworth of Wentworth, Woodhouse, Yorkshire, was b. April 13, 1593. In 1611 he married lady Margaret Clifford, eldest daughter of the earl of Cumberland. Subsequently he was chosen member of parliament for the co. of York. In 1615 he was appointed *custos rotulorum* for the West Riding of the same county. Being again returned to parliament for Yorkshire in 1621, shortly after his election he took up his residence in Lon-

don. Slighted by the duke of Buckingham, who then ruled the court and cabinet of Charles I., Wentworth signalized himself as an opposer of the administration. In 1626 he was made sheriff of his county, with the view of preventing him from attending parliament. So resolutely did he oppose the arbitrary royal loan, exacted in the following year, that the government deemed it advisable to put him in prison. But Buckingham was little aware of the energy of his opponent. Strafford, having obtained his release, came to the following parliament, resolved to make his power felt both by king and minister. He spoke eloquently on the question of grievances, and was conspicuous in obtaining the royal assent to the petition of right. He was obviously a man worth gaining; and his patriotism, if it had any genuine element, was, unhappily not strong enough to withstand the temptation now held out to his personal ambition. With his elevation to the peerage as baron Wentworth, in 1628, he seems not only to have lost all solicitude for popular liberty, but openly to have become its most determined enemy. As president of the "council of the north," he seems to have abused his powers not only for political purposes, but often simply to gratify his own pride. The legality of the jurisdiction exercised by the council created by Henry VIII. was altogether very doubtful, and interdicts against it were at various times applied for from the courts at Westminster. Strafford declared openly that he would "lay by the heels" any judge presuming to interdict the council from the exercise of such powers as he chose to hold that it possessed. Nevertheless, this was done by judge Vernon. In 1631 Strafford was made deputy of Ireland, and in 1639 earl of Strafford and lord lieutenant of Ireland. According to his views, that country belonged to the crown by right of conquest, and neither the natives nor the descendants of the conquerors themselves had any rights which could interfere with its sovereignty. His government was of despotic violence, but the administration of justice, in ordinary cases, was prompt and vigorous. Outrage was suppressed and commerce flourished under his strong hand. Understanding fully the feelings, policy, and resources of the party to which he had originally belonged, Strafford had matured a vast political scheme, to which, in his confidential correspondence, he gave the expressive name of "thorough." His object was to do in England what Richelieu was doing in France—to make Charles as absolute as any continental monarch; to put the estates and personal liberty of the whole people at the disposal of the crown; to deprive the courts of law of all independent authority; and to punish with merciless severity all who murmured against the government, or who applied to any tribunal for relief from its despotism. Happily the people of England were too strong for him. On his entering the house of peers on the meeting of the long parliament in 1640, the message from the house of commons was called in, and Mr. Pym, in the name of the commons of England, impeached "Thomas, earl of Strafford," of high treason. This course was afterward abandoned, and the commons proceeded by bill of attainder. It passed the house on April 21, 1641. Immediately after it passed in the house of lords, and received the royal assent. Strafford certainly merited his fate, but nothing can excuse the cowardice of the king. The earl was executed on May 12, 1641. The attainder was reversed in the reign of Charles II., and his son succeeded to the honors. See Hallam's *Constitutional History*; Macaulay's *History of England*, with authorities cited in these works.

STRAIGHT UNIVERSITY, in New Orleans, was founded by Mr. Seymour Straight exclusively for colored students. It was organized in 1869 under the auspices of the Congregationalists. It has about 22 instructors and 600 pupils.

STRAIN, ISAAC G., 1821-57; b. Penn.; entered the navy. In 1845 he explored Brazil, in 1848 Lower California, and in 1849 South America between Valparaiso and Buenos Ayres. He afterward led an expedition across the isthmus of Panama to find a route for a ship canal. This expedition suffered greatly from hardships. In 1856 he made soundings to show the feasibility of an Atlantic cable.

STRAITS SETTLEMENTS are the British settlements in the straits of Malacca, comprising Singapore (q.v.), Malacca (q.v.), and Prince of Wales (q.v.), or Penang, including the Province Wellesley and Dindings. Area, 1472½ sq. miles; pop. '91, 507,696. In addition to these, in 1896 the British government concluded a treaty with the native states Perak, Selangor, Pahang, and Negri Sembilan, by which these states were all brought into one confederation under the authority of a British Resident General. Area of this new territory, about 35,500 sq. miles; pop. 418,527. The Straits Settlements were transferred from the control of the Indian government to the colonial secretary in 1867. The seat of the government is at Singapore.

STRAKOSCH, MAURICE and MAX, two brothers well known in the U. S. as impresarios and conductors. The eldest, Maurice, b. Lemberg, 1825, organized various concert and opera troupes, which visited the U. S., 1855-59. In the latter year he brought out Adelina Patti, whose success was so great that he took her on a tour through Europe. He subsequently married her sister Amalia. On Maurice's departure, Max, who had hitherto acted as business agent for his brother, became manager, in his turn, of numerous Italian and English opera companies, and introduced to the American public many famous modern singers. Maurice S. d. 1887; and Max in 1892.

STRALSUND, a fortified t. and seaport of Prussia, province of Pommern, is situated on a narrow strait called the Strela Sunde, which divides the mainland from the island of Rügen. It forms an island, partly surrounded by the sea, and partly by large pools of salt water, and is connected with the mainland by three moles. The natural strength of the place is greatly increased by formidable fortifications, which, however, have recently been in part removed. Right in front of the harbor lies the fortified island of Dänholm. Stralsund has narrow, but pretty regular streets, and many of the houses are finely gabled, giving the town a quaint and ancient look. Stralsund carries on a large export trade, and produces leather, gloves, sugar, starch, mirrors, canned fish and vegetables, earthenware, and playing cards (the United Stralsund card manufactory producing nearly two million packs a year). Pop. '95, 30,097.

STRAMONIUM, the specific as well as common name of *datura stramonium*, otherwise called Jamestown weed, jimson weed, and thorn-apple. The *datura* is a genus of *solanaceæ*, or the nightshade family, which includes the common potato, tomato, egg-plant, bitter-sweet, common nightshade, horse-nettle, ground cherry, and tobacco. *Stramonium*, or Jamestown weed, is very unequally distributed, being common in some localities, and rare in others; but it generally grows in abandoned gardens and waste places, especially where ashes have been dumped, or where the soil is rich in potash, for this is the mineral ingredient in which it delights, as do the other members of the *solanaceæ*, especially the potato. In the suburbs of some cities (e.g., Brooklyn) it grows luxuriantly alongside old piles of ashes. Generic characteristics: calyx prismatic, 5 toothed; corolla funnel form, with a large and spreading 5 to 10 toothed, plaited border; stigma two lipped; pod globular, prolate, one and a half to two inches long, prickly, 4 valved, 2 celled, with thick placenta, projected from the axis into the middle of the cells, and connected with the walls by an imperfect false partition, so that the pod is 4 celled, except near the top; numerous flat, angular, black seeds, which contain a powerful narcotic poison, having peculiar properties. Its native country is not known, but most botanists believe it to be Asia. De Candolle refers it to the countries bordering on the Caspian sea; others regard it as coming from northern India. It is a coarse, strong, vigorous, branching weed, growing from two to 6 feet high (in rich ground), leaves ovate, sinuate toothed, or angled. The alkaloid *daturia* was found in the seeds by Geiger and Hesse in 1833, and subsequently in other parts of the plant. Von Planta in 1850 pronounced this alkaloid to be identical with atropia in composition, solubility, and fusibility; but the physical experiments of Von Schroff in 1852 showed that the two alkaloids, though acting qualitatively alike, are very unequal in their effects, *datura* being about twice as strong as atropia (the active principle of belladonna). Trommsdorff obtained *stramonium* as a white, tasteless powder, insoluble in water, soluble in ether, sparingly soluble in alcohol. The other constituents of the seeds are about 25 per cent of a bland, fixed oil, mucilaginous, resinous, and other common principles. The physiological action of stramonium varies with the animal to which it is given. Several kinds of caterpillars devour it without injury, and goats browse upon it. A decoction of the leaves applied to the skin of a young rat has produced alternate debility and convulsions. Large doses given to horses have produced drowsiness and even death. On man, stramonium and belladonna are almost identical in their action. The powdered leaves of stramonium in two-grain doses increase the fullness and frequency of the pulse, make the skin warm and the hands and face moist. Five-grain doses produce dilatation of the pupils, difficulty of speech, nausea, thirst, dryness of the throat, catharsis, increased flow of urine, and feverishness. Larger doses cause high fever and delirium, the patient sometimes becoming violent. There is dizziness, and the face is much flushed and often swollen, the eyes bright, the conjunctiva red, the pupils dilated and the sight confused. Sometimes the skin is covered with a bright red eruption, which may be followed by minute vesicles, or have the appearance of erysipelas or of measles. Sometimes there are hydrophobic phenomena, and convulsions will occur on attempting to drink. In rare fatal cases, the phenomena of excitement are succeeded by stupor, insensibility, and sometimes paralysis. There is, in no case, any tendency to sleep but, on the contrary, persistent insomnia. Among the perversions of the senses, is that of all black objects appearing green. At one time stramonium was believed to be a valuable remedy in insanity, but not now, although there are isolated cases where its use has been attended with benefit. In some cases of epilepsy it is useful. In spasmodic asthma there is no doubt of its frequent beneficial action. The skepticism in regard to this has no doubt arisen from failure to diagnose the variety of asthma. To be of use it must be given in the purely spasmodic cases. The common method of administration is smoking the dried leaves in a tobacco-pipe, or inhaling the smoke from a chafing-dish. It has been used internally to relieve whooping-cough, dysmenorrhœa, and retention of urine. In the absence of belladonna, or atropia, it may be used to produce dilatation of the pupil in ophthalmoscopic operations. The physiological and clinical antidote to stramonium is opium or its alkaloid morphia. Sometimes 15 grs. of muriate of morphia have been given.

STRANGE, Sir ROBERT, eminent as an engraver, was born in Pomona, one of the Orkney islands, July 14, 1721. After some little abortive study of law at Edinburgh, he was apprenticed to an engraver there of the name of Cooper, under whom he made rapid progress. In 1745 he deserted art for arms, joining the army of Charles Edward, not so much from enthusiasm in his cause, as to find favor with a Miss Isabella Lumisden, who would only consent to be gracious to him on that romantic condition. The only exploit

recorded of him in this relation is not one of glorious battle. After the final collapse of the adventure, he was in hiding in the house where Miss Lumisden resided; and on occasion of its being searched by the soldiery, he shrouded himself under the folds of her ample petticoat, and thus cleverly evaded detection. It is extremely satisfactory to know that very soon after the lady requited his heroism by marrying him. He now went abroad with his wife, and at Paris he prosecuted his art under the tutelage of the celebrated Le Bas, and afterward of Descamps. In 1751 he returned to Britain, and settling himself in London, speedily attained the very highest rank in his profession. On again going abroad in 1760 to execute plates of the most famous pictures of the old masters, his eminence was recognized by the academies of Paris, Rome, Florence, Bologna, and Parma, all of which conferred on him the honor of membership; and subsequently in 1787, the distinction of knighthood testified to the high favor he found in his own country. After a life of honorable and successful industry, he died on July 5, 1792, leaving a handsome fortune to his family. To this day, Strange is ranked at the very head of British engravers, and his reproductions of the nobler specimens of the old masters are much prized by the connoisseur. In the very amusing work entitled *Memoirs of Sir Robert Strange, Knight, Engraver, and of his Brother-in-law, Andrew Lumisden, Private Secretary to the Stuart Princes* (2 vols., 1855), by James Dennistoun of Dennistoun, a full account will be found of him, with an intelligent criticism of his chief works.

STRANGE, ROBERT, LL.D., 1796-1854; b. Va.; educated at Hampden-Sidney coll.; studied law; established his practice in Fayetteville, N. C. He was, in 1822-23 and 1826, a member of the state house of delegates; 1826-36 was judge of the superior court; 1836-40 was U. S. senator. Resuming practice of his profession in Fayetteville, he became solicitor of the 5th judicial district of the state. The legends of the Cherokees were embodied by him in a novel entitled *Eoneguski*, privately circulated.
